PORT-FLANGE. A wooden batten coved out and fitted on the ship's side, over the ports, to prevent the water from running into the port. A *port-riggle*.

PORT-PENDANTS. Ropes spliced into rings on the outside of the port-lids, and rove through leaden pipes in the ship's sides, to work the port-lids up or down by the tackles.

PORT-PIECE. An ancient piece of ordnance.

PORT-SASHES. Half-ports fitted with glass for the admission of light into cabins.

PORT-SILLS. Pieces of oak dovetailed into the frame-timbers to form the upper and lower part of the ports.

PORT-STOPPER. A heavy piece of iron, made to swing round and close the port in a turret-vessel.

Port au Prince, the principal seaport and capital city of Hayti, is situated at the head of Gonaïves Bay, in lat. 18° 35′ N., lon. 72° 18′ W. It is partially fortified. The vicinity is marshy, and the climate unhealthy. It is the seat of the greater part of the foreign trade of the island, the annual value of the imports being about $1,200,000. Pop. 20,000.

Porter, B. H., Lieutenant U.S.N. See PRESTON.

Porter, David, Commodore U.S.N. Born in Boston, February 1, 1780; died in Pera, Turkey, March 28, 1843. At the age of 16 he made a cruise to the West Indies in a merchant vessel, and during the two succeeding years made several voyages in merchant ships. He was twice impressed by British vessels of war, and on each occasion took the first opportunity to escape and work his passage home. In April, 1798, he obtained a midshipman's appointment in the navy. Midshipman Porter served in the frigate "Constellation" in her action with the French frigate "Insurgente," February 9, 1799. In October, 1799, he was promoted to the grade of lieutenant, and ordered to the West India Station as first lieutenant of the schooner "Experiment." On the 1st of June, 1800, this vessel, with several sail of merchantmen under convoy, lay becalmed in the bight of Leogane, in the island of San Domingo. While thus lying, they were attacked by 10 piccaroon barges, each containing 40 men, with swivels mounted in the bows and on the quarters. The "Experiment" had been disguised to look as much like a merchant ship as possible, and the piccaroons steered for her with the evident intention of boarding. At this critical moment her commanding officer showed the white feather, and was about to surrender to a force he considered it hopeless to contend against, when Lieut. Porter, backed by Lieut. Blake, protested so vigorously that it was determined to defend the ship and convoy to the last; and after a combat which continued for 7 hours, the pirates having lost 2 of their barges sunk by the schooner's fire, and many of their men killed and wounded, withdrew from the fight. Shortly after the affair of Leogane, Lieut. Charles Stewart (Old Ironsides), was ordered to command the "Experiment," and for some months these two officers, Stewart and Porter, who afterwards became so famous, served together in the little schooner, and while thus serving captured the French schooner-of-war "Diane." In October, 1803, Lieut. Porter was captured in the frigate "Philadelphia," and remained a prisoner in Tripoli until peace was proclaimed.

In 1806 he was promoted to master-commandant, and on the 10th of March, 1808, Commander Porter was married to Miss Anderson, of Chester, Pa. In 1812 he was promoted to the grade of captain. Between the years 1809 and 1812, Capt. Porter was a large portion of the time on special duty in New Orleans, and while there he made the acquaintance of the Farragut family, and took under his special protection young David Farragut, who became in after-years the most renowned of our admirals. At the beginning of hostilities in 1812, Capt. Porter sailed from New York in command of the "Essex," 32, and in a short cruise captured several British merchantmen and transports. Soon afterward he fell in with and captured the British corvette "Alert," 20. On December 11, near the equator, he captured the British government packet "Norton," with $50,000 in specie on board. In January, 1813, Capt. Porter proceeded to the Pacific with the intention of doing all the damage he could to the English whale-fishery in that ocean.

On March 25, he captured the Peruvian privateer "Nereyeda" of 19 guns, which had taken two American whalers and had their crews on board as prisoners. They were transferred to the "Essex," and the armament and ammunition of the "Nereyeda" thrown overboard, when she was released. After this, Capt. Porter cruised about 10 months in the Pacific, capturing 12 British ships employed chiefly in the sperm-whale fishery, and for a time that important British interest in the Pacific was almost destroyed. The "Georgiana," captured whaler, was converted into a vessel of war called the "Essex, Jr.," and cruised with the "Essex." On February 3, 1814, the "Essex" and "Essex, Jr." arrived at Valparaiso. On the 8th, H. B. M. frigate "Phœbe" and sloop "Cherub" arrived and anchored near the "Essex," and after obtaining supplies cruised off Valparaiso 6 weeks. On March 28 the "Essex" made an attempt to get to sea, but in doubling a headland was struck by a squall, which carried away her fore-topmast and caused the loss of several of her crew. In this crippled state the ship anchored less than 3 miles from the town, only half a mile from the shore, and while within neutral waters was attacked by the "Phœbe" and "Cherub," the first shot being fired at 3.54 P.M. The "Phœbe's" fire proved very destructive, as she occupied a position where her

long guns could rake the "Essex," while that vessel could hardly bring a gun to bear against her, the "Cherub" meanwhile pouring in a galling fire. The latter vessel, however, soon found her position such a hot one that she was driven to leeward, near the "Phœbe," where both vessels kept up a raking fire on the American frigate. Capt. Porter now got three long 12-pounders out of the stern port, and these guns were so well worked that in half an hour both the attacking vessels hauled off to repair damages. The enemy's vessels having finished repairs, took up their position on the starboard quarter of the "Essex," out of reach of her carronades, and where her long guns could not be brought to bear upon them. Their fire was very severe, and Capt. Porter had no alternative but to get under way and become the assailant. The flying-jib was set and the cable cut, and the "Essex" ran down upon her assailants, and for a short time succeeded in closing with them, so as to use her carronades with such effect that the "Cherub" was forced to haul off, and for a few minutes the hope was entertained that the enemy were so far disabled as to permit the "Essex" to escape; but the hope proved a vain one, as the "Cherub" kept up a destructive fire with her long guns, and the "Phœbe" chose the distance best suited to her long 18's, where, out of the range of the carronades of the "Essex," she kept up a deliberate and destructive fire. The action had now lasted over two hours, and the "Essex" lay like a target, riddled by every shot from the enemy. The crew were completely exhausted, and had become so weakened in numbers that they entreated the captain to surrender in order to save the lives of the wounded, and accordingly, at 20 minutes past 6, the order was given to haul down the colors. The contest throughout was a most unequal one, the enemy having the advantage in every way. In this action young Farragut, who was serving on board as a midshipman, fought most bravely, and was especially commended by Capt. Porter in his official report.

The "Essex, Jr." brought the survivors of the action to the United States, where Capt. Porter was received with great honors. His narrative of this cruise was published in New York in 1822. His son, Admiral Porter, describes it most vividly in his life of Commodore Porter, published in Albany in 1866. From April, 1815, to December, 1823, Capt. Porter was a member of the Board of Navy Commissioners, which post he resigned to take command of the expedition fitting out against pirates in the West Indies. In October, 1824, upon evidence that a quantity of valuable goods had been stored by pirates at Foxardo, in the east end of Porto Rico, Commodore Porter dispatched the schooner "Beagle" to investigate the matter, but the officers on landing were arrested and thrown into prison. Commodore Porter on hearing of this outrage sailed for the island, landed a force of 200 men, and demanded an apology, which was promptly given. The authorities at Washington deeming he had exceeded his powers brought him before a court-martial, and he was sentenced to 6 months' suspension. He soon after resigned, and entered the service of Mexico as commander-in-chief of the naval forces, at a salary of $25,000 per annum. He remained in this service until 1829, when having been treated most treacherously by the Mexican officials, and betrayed by those he had the most reason to expect good faith from,—the very officers he had taught the rudiments of their profession turning against him because he was a foreigner,—Commodore Porter resigned his position, returned to the United States, and was appointed by President Jackson consul-general to the Barbary powers, from which post he was transferred to Constantinople as resident minister there, which office he held when he died. His remains are interred in Woodland Cemetery, West Philadelphia.

Porter, David Dixon, Admiral U.S.N. Born June 8, 1813, in Chester, Pa. In 1824 he accompanied his father, Commodore David Porter, in the "John Adams," and was with him during that memorable expedition which forever suppressed piracy in the West Indies. The resignation of Commodore Porter from the U. S. navy on account of the failure of our government to sustain him in his energetic measures, resulted in his becoming admiral of the Mexican navy (1826), that people being then engaged in their struggle for independence.

David D. Porter was appointed a midshipman in the Mexican service. He obtained service afloat with his cousin, Capt. D. H. Porter, who commanded a Mexican vessel cruising against Spanish commerce. After a most adventurous and successful cruise, Capt. Porter was obliged to return to the rendezvous at Key West on account of a mutiny on board. Its early discovery was due to the precocity of Midshipman Porter, who had then arrived at the age of 14 years. In the struggle with the mutineers Midshipman Porter handed the pistols and sword to Capt. Porter, who by his coolness and determination soon disabled the ringleaders and brought all to terms. Of the whole crew, only three remained faithful.

In order to secure the prisoners and prevent them from meddling with their irons, Capt. Porter cut holes in the poop-deck so as to allow the feet of the prisoners to go through into the cabin, where they were ironed together. The captain, assisted by Midshipman Porter and three men, succeeded in running the Spanish blockade and bringing the vessel and captured property into Key West. During the spring of 1828, the brig "Guerrero," 22 guns, Capt. D. H. Porter, was fitted out to cruise against Spanish commerce. Midshipman Porter was again detailed to duty under Capt. Porter. The "Guerrero" had a fine crew of 186 men. Soon after arriving on the coast of Cuba, Capt. Porter attacked two Spanish brigs of superior force convoying a merchant fleet. The firing brought a Spanish 64-gun frigate to the rescue of the convoy, thus robbing Capt. Porter of the fruits of a victory fully secured, and forcing him to fight a vessel infinitely the superior of the "Guerrero." After a desperate resistance the brig was forced to surrender. In this action Capt. Porter and nearly half his crew were killed, and all the officers were more or less severely wounded. The survivors were imprisoned in the guard-ship at Havana. Midshipman Porter, after a short imprisonment, was allowed to go to Vera Cruz, and soon after (1828) he returned to the United States. It is a singular fact that the nation is indebted to Commodore David Porter not only

for his own brilliant career, but also for the two most distinguished naval officers of recent years, as both Farragut and the subject of this sketch were brought up under the personal care of that officer, and under his command fought their first battles.

David D. Porter was appointed midshipman in the U. S. navy February 2, 1829. He served on the European Station until 1835.

Many amusing stories are told of his career as a midshipman, although the commodore of the squadron and the captain of his ship may not have fully appreciated them.

In 1836 he was promoted to passed midshipman. He served on the coast survey until he was promoted to lieutenant, February, 1841. Served at sea and at the Naval Observatory until 1846, when he was selected by the Secretary of State to go on a secret mission to Hayti to report upon the condition of affairs in that island. This he did in a very thorough manner.

He served with distinction during the entire Mexican war as first lieutenant, and afterwards as commanding officer of the steamer "Spitfire." He was engaged in every action on the coast. After that war he obtained a furlough from the Navy Department, and for some years commanded steamers on important passenger lines. His vessels never met with an accident.

The Secretary of War during Mr. Buchanan's administration selected him for the duty of importing camels into this country; 84 were brought over in the U. S. ship "Supply." The breaking out of the war found Porter a lieutenant on shore duty. In a little over two years he was a rear-admiral, commanding a squadron. As a lieutenant commanding the "Powhatan," under confidential orders from President Lincoln, he assisted in the relief of Fort Pickens. Soon after he was made a commander. The Department was undecided in regard to the officer who should command the expedition against New Orleans. Some foolish doubts had been expressed as to Farragut's loyalty. From the "Life and Letters" of Admiral Farragut recently published, we learn that "Commander David D. Porter, who had been taken into the confidence of the Secretary, was sent as an intermediary to ascertain whether the proposed service would be agreeable. The result was that Farragut was ordered to report in person at the seat of government," and soon after received his preparatory orders to command the Western Gulf Blockading Squadron. From the same authority it appears that the Secretary informed Flag-Officer Farragut that "there will be attached to your squadron a fleet of bomb-vessels and armed steamers enough to manage them; all under command of Commander D. D. Porter, who will be directed to report to you." This was the first of the famous mortar fleet which did such good service.

The mortar fleet, consisting of 21 mortar-schooners, each carrying a 13-inch mortar, and 5 steamers as convoys, reached the mouth of the Mississippi during March, 1862. Soon after, 4 of the vessels of Farragut's fleet arrived, and preparations were made for the attack on Forts Jackson and St. Philip. The vessels of the mortar fleet were towed to proper range near the forts on the 18th of April, and for six days and six nights fired continuously on the rebel works, the officers and men being divided into three watches. Six thousand bombs were exploded in the forts, and the fire from them had destroyed everything combustible in the works; their garrisons had become so demoralized that in the judgment of the flag-officer the passage of the fleet was practicable, and it was successfully accomplished during the night and early morning of April 24.

Flag-Officer Farragut having destroyed the enemy's fleet of 15 vessels, proceeded to New Orleans, which place he reached next day. The reduction of the forts was left to Commander Porter. They surrendered to him on the 28th of April, after one day's bombardment. Commander Porter zealously assisted Flag-Officer Farragut in all his operations between New Orleans and Vicksburg, and at the latter place bombarded the forts very effectively, enabling the fleet to pass safely. Admiral Farragut, in his official report of June 30, 1862, says, "The Mortar Flotilla have never done better service than at Vicksburg, notwithstanding the imperfection of their fuzes. I have no doubt that they did the forts on the heights great damage, and on the morning of the attack did much to distract the fire from the fleet." In July, Porter was ordered with most of his mortar fleet to Fortress Monroe, but as there was no chance for immediate service at that point, he gave up the command of the Mortar Flotilla, which he had made famous, and was soon after ordered to the command of the Mississippi Squadron, as acting rear-admiral, September, 1862. He improvised a navy-yard at Mound City, and the small squadron of only a dozen effective vessels was soon increased to over 120, fully manned and officered by 1300 officers, only 25 being regular naval officers. The vessels were river-boats converted into efficient war-vessels, by covering them with light armor and putting heavy guns on them. The officers were chiefly Western steamboat-men, who, under Porter's rigid discipline, soon became valuable and trustworthy officers. In January, 1863, Admiral Porter's fleet, in co-operation with Sherman's army, captured Arkansas Post, a very formidable fort on the Arkansas River, 50 miles from its mouth, for which Porter received a vote of thanks. Soon after he ran past the batteries at Vicksburg and succeeded in capturing the rebel forts at Grand Gulf. This put him in close communication with Gen. Grant, who, on the 18th of May, by means of the fleet, put himself in the rear of Vicksburg, and from that time the energies of the army and navy were devoted to the capture of that stronghold, which was finally accomplished July 4, 1863. Porter received the thanks of Congress and was commissioned a rear-admiral from that day.

During the remainder of 1863 the squadron of Rear-Admiral Porter was busy keeping the Mississippi River open, and the next spring he went up the Red River to co-operate with Gen. Banks, but the military part of the expedition failed, and the retreat of the army left the gunboats in a bad way, being above the rapids after the fall of the river. However, the energy of Rear-Admiral Porter, and the skill of Lieut.-Col. Bailey, an old river engineer, saved the fleet by building a dam below the rapids, thus sufficiently deepening the water so as to enable the gunboats to pass down safely.

Admiral Porter now possessed the entire confidence of the Department and of the nation, and was ordered to the command of the North Atlantic Blockading Squadron, which embraced within its limits Cape Fear River and the port of Wilmington.

A fleet comprising all the available vessels at the disposal of the Department was assembled at Hampton Roads. In December it sailed for Beaufort, N. C. On December 24, 1864, Rear-Admiral Porter, with a force of 35 vessels, 5 of which were ironclads, and a reserve force of 19 vessels, commenced the bombardment of the forts at the mouth of Cape Fear River, and silenced them in an hour and a quarter.

General Butler, who commanded the military forces, after a reconnoissance, decided that Fort Fisher could not be carried by assault. He therefore returned with his command to Hampton Roads. Admiral Porter, aware of the necessity of reducing the works and the great importance of closing the port of Wilmington, and confident that with adequate military support the fort could be carried, earnestly requested that the enterprise should not be abandoned. A second military force was promptly detailed, composed of about 8500 men, under command of Major-Gen. A. H. Terry. This force arrived off Fort Fisher on the 13th of January. Offensive operations were at once resumed by the naval force, while the troops landed and intrenched themselves. The bombardment was continued throughout the 14th with an increased number of vessels. The 15th was the day decided upon for the assault. During the morning of that day 44 vessels poured an incessant fire into the fort. There was besides a force of 14 vessels in reserve. At 3 P.M. the signal for the assault was made. Desperate fighting ensued, traverse after traverse was taken, and by 10 P.M. Fort Fisher was captured.

Fourteen hundred sailors and 500 marines were landed and participated in the direct assault. Seventy-five guns, many of them superb rifle pieces, and 1900 prisoners were the immediate fruits of the victory.

Rear-Admiral Porter received the thanks of Congress for the Fort Fisher affair, being the fourth vote of thanks received by him during the war, including the general one for the capture of New Orleans.

He was promoted to vice-admiral in July, 1866, and was ordered as superintendent of the Naval Academy. His energy and ability first brought that institution into prominence, and so changed its character that it has ever since been considered the best naval college in the world.

Upon the election of Gen. Grant to the Presidency, Vice-Admiral Porter was detailed for duty in the Navy Department under Secretary Borie. But upon the withdrawal of Mr. Borie from the Cabinet, he, in a short time, also withdrew from the Department. In August, 1870, he was promoted to admiral of the navy, and since that time has devoted himself to his duties as senior officer of the navy.—*R. M. G. Brown, Lieutenant U.S.N.*

Port-fire. A stick of highly inflammable composition, consisting of nitre, sulphur, and mealed powder. It is now used principally for life-buoy lights on account of its ability to resist the action of water. In early days it was used in firing guns. It forms good material for incendiary shell.

Portland, the commercial metropolis of Maine, is situated in Cumberland County (of which it is the county-seat), on Casco Bay, in lat. 43° 39′ 27″ N., and lon. 70° 15′ 40″ W. The peninsula on the west shore of Casco Bay, on which the city is located, is about 3 miles in length, by an average breadth of three-quarters of a mile. The harbor is one of the best on the Atlantic coast, is well protected, of sufficient depth to float the largest ships, and is open all the year. It is defended by Forts Preble, Scammel, and Gorges. The city has an extensive coastwise and foreign trade, the annual value of the exports being about $22,000,000, and the imports $20,000,000. There are 2 dry-docks and other facilities for repairing ships, and ship-building was for a long time a leading pursuit. Railroad-cars, locomotives, marine and other engines are important articles of manufacture. Pop. 37,000.

Port Royal. See NAVAL STATION.

Portsmouth, a seaport town and the principal naval station of England, is situated on Portsea Island, at the entrance to its famous harbor, in lat. 50° 48′ N., and lon. 1° 16′ W. This town, inclosed as it is by bastioned ramparts, faced with masonry, surrounded by trenches and outworks, is the most perfect fortress in Great Britain. The town of Portsea is separated from Portsmouth by a creek, and is also inclosed by a line of fortifications. Within this town is the naval dock-yard, containing basins, wet- and dry-docks, large warehouses, anchor-forges, iron- and copper-mills, rope-houses, etc. In the dock-yard are also the royal naval college, and the residence of the port-admiral. Between the dock-yard and Portsmouth is the gun-wharf or arsenal, containing an armory, and artillery and ammunition depots. The harbor is large enough to hold the entire navy of Great Britain, although at its entrance it is only 220 yards wide. Pop. 115,000. See ESTABLISHMENTS, NAVAL, OF GREAT BRITAIN.

Portsmouth, the commercial metropolis and only seaport of the State of New Hampshire, is situated on a beautiful peninsula, formed by the Piscataqua River, and on the right bank of that river, about 3 miles from the ocean. The harbor, which lies between the town and the mouth of the river, is capacious, deep, easy of access, and is much frequented by vessels in bad weather. Sand-bars or ice cannot form owing to the rapid tides. The main entrance to the harbor, between the mainland and Great Island, is defended by earth-works on Gerrish's Island and Jeffrey's Point, and farther up the harbor are two stone forts (Constitution and McClary). A U. S. navy-yard is located here, for a full description of which see NAVY-YARD, PORTSMOUTH, N. H. The leading articles of manufacture are cotton, cloth, hosiery, shoes, etc. Pop. 10,000.

Portsmouth, Norfolk Co., Va., is on the left bank of the Elizabeth River, nearly opposite Norfolk. The river, which is about two-thirds of a mile wide, forms a good harbor, which admits vessels of the largest size. Large steamboats ply daily between Baltimore and Portsmouth. A naval hospital is located here, and in the adjacent suburb of Gosport the navy-yard commonly known as the Norfolk Navy-

Yard is situated. (See NAVY-YARD (GOSPORT), NORFOLK, VA.) Pop. 11,000.

Portugal, Navy of. Not until Columbus had settled the question of the rotundity of the earth could the Portuguese mariners be induced to sail as far as the equinoctial line. In the few trips made in a southerly direction they had encountered water-spouts, beheld a comet, and experienced a degree of heat which alarmed them exceedingly,—the more ignorant and superstitious believing they were approaching the region of eternal flames. But the return of the vessels which had carried the Genoese explorer to San Salvador reassured the sailors of Lusitania, and raised the hopes of the people that a path might be found to India in an easterly direction. Then it was that John II. caused ships to be constructed for the purpose of contending with the winds and the waves of the tropics, and Bartolomew Diaz was selected to make the first attempt. The passage along the west coast of Africa was tolerably smooth, but off the southernmost point the opposition of the winds was so great that no other name could be found for the locality than *Tormentoso*. The point, however, was settled that Diaz had been sent to determine. He had rounded the cape at the southern extremity of the African continent, and thus demonstrated that there was a clear passage to India. The *Capo de buon Esperanza* was the name given to the cape, and Diaz went back to carry tidings of "golden times and happy news of price." Not an hour was lost in taking advantage of the discovery. Vasco da Gama was appointed to proceed to India with three ships of 200, 120, and 100 tons burden, and authority to open a traffic with the people who had theretofore sent their produce and manufactures to Europe only by the Red Sea and Persian Gulf, or to war with them if they manifested hostile inclinations. Da Gama's voyage to the west coast of India was a success in every way; but it aroused the jealousy of Holland and England, and justified the creation of a small navy in the event of collision with those powers. There is little to chronicle of the operations of the Portuguese navy at any time, and its strength at the present day consists of 1 armored ship, 10 screw-corvettes, 9 gunboats, 1 sailing-frigate, 1 sailing-corvette, 3 transports, 2 tugs, and 1 yacht. The ironclad "Vasco da Gama," built at the Thames Iron Ship-building Yard, London, and launched in 1876, is the most important vessel of this navy; the length of the vessel between perpendiculars is 200 feet; breadth, 40 feet; depth of hold, 25 feet; draft of water forward, 17 feet 6 inches; aft, 19 feet; displacement, 2479 tons; thickness of iron on the armored belt and battery, 9 inches; thickness of teak backing, 10 inches. The motive machinery consists of a pair of vertical compound engines for each of the two screw-propellers. At their trial they developed 3625 horse-power, and the ship realized a speed of 13¼ knots per hour. The ship is fitted with a ram, and her armament consists of Krupp breech-loading rifles, —two of 10¼ inches calibre and 21 tons weight, one 6 inches calibre and 4½ tons weight, and two 40-pounders. The "Estephania" is the largest of the corvettes, but is an old vessel. The only modern corvettes are the "Rainha da Portugal" and the "Mindello," sister ships, 170 feet long, 36 feet beam, having single screw-propellers, operated by compound engines of 900 indicated horse-power, and the armament of each consists of two 4½-ton and six 40-pounder Armstrong guns. Two of the gunboats,—the "Mandovè" and "Bengo,"—built in 1879, are each 123 feet long, 24 feet beam, and 334 tons displacement, and are armed each with one Armstrong pivot-gun and two 20-pounders. The other corvettes and gunboats are of old date. The naval arsenal is located at Lisbon, and comprises the ship-yard, the depots of arms and provisions, the museum, and the naval school. The *personnel* is comprised as follows: 1 vice-admiral, 5 rear-admirals, 17 captains of line-of-battle ships, 26 captains of frigates, 32 lieutenant-captains, 57 first-class lieutenants, 78 second-class lieutenants, 7 engineers of marine construction, 57 mechanicians, 22 surgeons, 38 paymasters, and an active force of 3950 enlisted men, including marines.

Portuguese Man-of-war. A beautiful floating acalephan of the tropical seas; the *Physalis pelagica*. See PHYSALIA.

Position. The position of a ship at sea is determined generally by the intersection of two right lines. These lines may represent *latitude* and *longitude*, two *lines of equal altitude*, etc. When in sight of land the position is determined by *cross-bearings*, by *one* bearing and a *line of equal altitude*, by any line and the depth of water, etc.

Post-captain. See CAPTAIN.

Pouches. Wooden bulk-heads across the hold of cargo-vessels, to prevent grain or light shingle from shifting.

Pound. A lagoon, or space of water, surrounded by reefs and shoals, wherein fish are kept, as at Bermuda.

Pound-and-pint Idler (*Eng.*). A sobriquet applied to the purser.

Pout. A sea-fish of the cod kind, about a foot in length; called also the *whiting*. It has the power of inflating a membrane which covers the eyes and neighboring parts of the head. An American fish of the genus *Pimelodus* (*P. cattus*); catfish; horned pout; bullhead.

Powder for the naval service is classed according to the size and shape of the grain, and designated as follows: hexagonal, cubical, mammoth, rifle, cannon, torpedo, small-arm, and shell powder. They are all, as a rule, made of the same proportion of ingredients,—*i.e.*, saltpetre 75, charcoal 15, and sulphur 10 parts. Hexagonal and cubical powder must weigh 70 to 75 granules to the pound; the other classes are sized by means of sieves, the holes in which vary in diameter from 1 to .02 of an inch. When powder is stored on shore, it is put up in barrels marked with maker's name, date and place of manufacture, initial velocity, density, pressure, kind, lot, and class. When stowed on board ship, it is put up in tanks, marked the same as the barrels from which the powder was taken. See GUNPOWDER.

POWDER-HOY. An ordnance-vessel expressly fitted to convey powder; it invariably carries a red distinguishing flag, and warns the ship for which the powder is intended to put out all fires before she comes alongside.

POWDER-MAGAZINE. See MAGAZINE.

POWDER-MONKEY. The boy who passed cartridges to the guns.

POWDER-TANK. A rectangular metallic case,

the sides and bottom being of sheet-copper (tin-coated), and the top of composition. Powder-tanks are made of 4 sizes, though the 200-pound tank is regarded as the standard size for service, the others being issued in special cases only. The calibre, number, and weight of the charges are stenciled upon the lid end, and on the upper side are the marks corresponding to the marks on the barrel from which the powder was taken. In order to distinguish more readily the tanks containing different kinds of powder, the following manner of painting the lids has been adopted:

Service charges.—Plain white, with calibre in red.

Saluting charges.—Half red, half white.

Torpedo charges.—Red T on a white ground.

Shell charges.—Red O on a white ground.

Howitzer charges.—Red H on a white ground.

Rifle charges.—Red R on a white ground.

Shell-powder.—Red S on a white ground.

POWDER-VESSEL. A ship used as a floating magazine.

Powell, Levin M., Rear-Admiral U.S.N. Born in Virginia. Appointed midshipman, March 1, 1817; served as midshipman in the Mediterranean, China Seas, and in the Gulf of Mexico and West Indies for the suppression of piracy.

Commissioned as lieutenant, April 28, 1826; served in the Mediterranean, West Indies, and Gulf of Mexico; before Charleston in the sloop "Natchez" during the nullification troubles; on coast of France pending the demand for payment of the French indemnity, 1834–35; in the West Indies and on the coast of Florida on the outbreak of the Seminole war,—commanding several expeditions against the hostile Indians,—in the last of these was wounded in a fight with them on the head-waters of Jupiter River, in January, 1837; received the thanks of the Navy Department for these services in Florida; commanded two surveying expeditions for the rectification of positions and soundings of the eastern coast and harbors of the Gulf of Mexico; and was commissioned commander, while on this duty, June 24, 1843; appointed assistant inspector of ordnance, October, 1843, and continued on ordnance duty until appointed to command of sloop "John Adams," which sailed for Brazil, July, 1849; served in her on the coast of South America and on the coast of Africa until return, in December, 1850; from 1851 to 1854, executive-officer of the navy-yard, Washington; was in command of the flag-ship "Potomac," cruising in North Atlantic and West Indies, to August, 1856.

Promoted to captain, September 14, 1855; inspector of contract steamers in 1858, and appointed captain of the frigate "Potomac" early in 1861, and sailed for Gulf Squadron, September of the same year; was retired by the act of December, 1861, and from command of the "Potomac," June 30, 1862; inspector of third light-house district from November 7, 1862, to October, 1866.

Commissioned as commodore, July 16, 1862.

Commissioned as rear-admiral, July 25, 1866, and on special service from 1867 to 1872. Retired March 1, 1862.

Power. The amount of work that can be done in a given time; it is the product of force, motion, and time. Its usual unit of measure is one horse-power, or 33,000 foot-pounds per minute.

Pozzolana. Volcanic ashes, used in cement, especially if required under water.

Præcursoriæ. Ancient vessels which led or preceded the fleets.

Prædatoriæ, or Prædaticæ. Long, swift, light ancient pirates.

Præsepe. A bright spot in Cancer which is resolved by the telescope into a cluster of stars; it is called also the *manger*, and sometimes the *beehive.*

Praia. The beach or strand on Portuguese coasts.

Pram, or Praam. A lighter used in Holland, and the ports of the Baltic, for loading and unloading merchant ships. Some were fitted by the French with heavy guns, for defending the smaller ports.

Pratique. A Mediterranean term, implying the license to communicate with any place after having performed the required quarantine, or upon the production of a clean bill of health.

Prawn. A marine crustacean larger than a shrimp, much esteemed as an article of food.

Prayer-book. A small hand-stone used to scrub in confined spaces where a large holy-stone cannot be used. See HOLY-STONE.

Preble, Edward, Commodore U.S.N. Born at Falmouth Neck, the site of the present city of Portland, Me., August 15, 1761; died in Portland, August 25, 1807. He made his first cruise in a privateer in 1777–78, and in 1779 entered the provincial marine of Massachusetts as a midshipman. He was serving on board of the "Protector" at the time of the action between that vessel and the English privateer "General Duff," and greatly distinguished himself in that affair.

Midshipman Preble was shortly afterward captured and confined on board the prison-ship "Jersey," in the harbor of New York. On being liberated he joined the Massachusetts vessel-of-war "Winthrop," on which he remained until 1782, winning new honors by boarding with 14 men an armed brig off Castine, and carrying her out under the fire of an English battery. After peace was declared he entered the merchant service, where he remained for 15 years.

In 1799 he was commissioned a lieutenant in the U. S. navy, and ordered to command the "Pickering," one of the squadron stationed at the Windward Islands. In June, 1799, he was commissioned as captain and given command of the "Essex," in which he convoyed home from Batavia a fleet of 14 vessels.

In 1803, Capt. Preble was ordered to command the squadron sent against Tripoli, his flag-ship being the "Constitution." On his arrival at Tangiers in October, he opened and successfully concluded negotiations which averted a war with Morocco. On November 12 he declared the blockade of Tripoli. The "Philadelphia," 38, Capt. Bainbridge, having run upon the rocks, was captured by the Tripolitans, but was destroyed at her anchorage in the harbor by Lieut. Decatur, on February 16, 1804. (See DECATUR, STEPHEN.) On August 3, his command then consisting of 15 vessels, including 8 small gunboats borrowed from the Neapolitan government, Preble made his first attack upon the enemy's gunboats, protected by batteries on shore. He captured 3 of the largest by boarding, and sunk

3 others. On the 7th he made a second attack, but with less success, the enemy keeping close within the harbor. One of Preble's gunboats was sunk. Another attack was made on the 28th, in which one of the Tripolitan gunboats was sunk and several driven ashore. Preble's flag-ship was closely engaged with the enemy's batteries, and for an hour lay within musket-shot of the mole. On September 3 the fourth attack was made, during which the "Constitution" was badly cut up, but Preble did not withdraw until he had inflicted great damage upon the enemy's batteries.

The "Intrepid," a ketch captured from the enemy, which Lieut. Decatur had used in destroying the "Philadelphia," was converted into a fire-ship, carrying 100 barrels of gunpowder in bulk in the hold, and on the deck immediately above the powder were laid fifty 13½-inch shells and one hundred 9-inch shells, with a large quantity of shot and fragments of iron of different sorts. Capt. Somers volunteered to take command of the "Intrepid," and Lieut. Wadsworth volunteered to serve with him. Commodore Preble personally superintended all the details of preparing this "powder-boat," and the night of September 4, that of the day which succeeded the attack last related, was selected for the purpose. When all was ready the "Intrepid" got under way and stood in towards the western passage, by which she was to enter. The last seen of her she was not a musket-shot from the mole, standing directly for the harbor, which a very few minutes afterwards was illuminated by a fierce light, followed by a concussion that shook the vessels in the offing from trucks to keels. A shot from the enemy's batteries had struck the kedge, and caused her premature explosion. None on board of her escaped, and with them perished the boats' crews from the "Constitution" and "Nautilus," that had been towed in to bring out the crew of the kedge after they had fired their vessels. The "Intrepid" perished a quarter of a mile from the spot she was intended to reach.

On the 10th of September Commodore Barron, in the "President," arrived at Tripoli and relieved Commodore Preble, who soon afterwards sailed in the "John Adams" for home. On his arrival he received a gold medal and a vote of thanks from Congress.

Preble, George Henry, Rear-Admiral U.S.N. Born in Portland, Me., and appointed a midshipman from that State, October 10, 1835; frigate "United States," Mediterranean, May, 1836, to November, 1838; sloop "Warren," frigate "Macedonian," sloop "Levant," and sloop "Erie," West Indies, January, 1839, until September, 1840; Naval School, at Philadelphia, January to June, 1841, when he was warranted passed midshipman, No. 7, in a class of 24; was acting lieutenant of schooner "Madison" and brigantine "Jefferson," on the Florida Expedition, from August, 1841, to August, 1842; went on several canoe expeditions into the everglades, and returned with the expedition sick; in receiving-ship "Ohio," at Boston, from October, 1842, to May, 1843; acting master and acting lieutenant in sloop "St. Louis," East Indies, and circumnavigating the world, May, 1843, to September, 1845; had charge of first American armed force ever landed in China, for the protection of American consulate and residents of Canton, June and July, 1844; acting master and executive of schooner "Petrel," in the Gulf of Mexico, May, 1846, to May, 1847; participated in surrender of Alvarado, Laguna, Tampico, and Panuco, and assisted at siege, etc., of Vera Cruz; returned to United States in ship-of-the-line "Ohio," sick, May 31.

Warranted as master, July 15, 1847.

Commissioned as lieutenant, February 5, 1848; returned to the Gulf in sloop "Saratoga," February, 1848, and came home sick, March, 1849; executive-officer of steamer "Legree," coast survey, April, 1849, to January, 1851; from January to August, 1851, in frigate "St. Lawrence," which conveyed American contributors to World's Fair, at London, and then conveyed our minister to Lisbon; commanding schooner "Gallatin," etc., coast survey, August, 1851, to December, 1852; December, 1852, to March, 1853, attached to the "Vermont," 74; on Japan Expedition and in China waters, from April, 1853, to August, 1856, in "Macedonian," and commanding chartered steamer "Queen"; assisted in the surveys of Jeddo and Hakodadi Bays; and also surveyed the harbor of Kealung, island of Formosa, his chart of which is published in the official report of the expedition; was on several successful expeditions against pirates in China, and received the thanks of Commodore Abbot and of the English admiral, Sir James Stirling, for the part taken by him in the one to Kulan; commanded an expedition to Foo-chow-foo, in the American steamer "Confucius," destroying several pirate junks; prepared sailing directions for Shanghai, which were published by the English and U. S. governments, and in several private editions; was light-house inspector of first district (coast of Maine and New Hampshire) from September, 1856, to October, 1857; at navy-yard, Charlestown, Mass., October, 1857, to September, 1859; executive-officer of steam-sloop "Narragansett," Pacific Squadron, September, 1859, until November, 1861, and ordered home at his own request to serve on the Atlantic coast; in January, 1862, took command of the steam-gunboat "Katahdin," equipping at Boston, and, March 29, reported to Admiral Farragut, West Gulf Squadron; passed the forts with the fleet, April 24, 1862, engaged the enemy's fleet, and was at the attack upon the lower defenses and at the surrender of New Orleans; participated in all of Farragut's operations on the river that year, as far as Vicksburg, assisting in destroying Grand Gulf; August 4, 1862, was transferred to the command of the steam-sloop "Oneida"; while steaming up the river above New Orleans, at night, August 8, the "Oneida" was purposely run into by the steamboat "Lewis T. Whitman," and although every effort was made to save her crew and passengers (70 of whom were saved), many lives were lost. Her rebel captain was sent to New Orleans in irons, and after his release served upon the steam-tug "Boston," and conveyed her to the rebels at Mobile.

Commissioned as commander, July 16, 1862; on the blockade off Mobile, August 25 to October, 1862; on August 29 he was left senior officer present, four vessels out of seven of our usual blockading force having left for coal and repairs; on September 4, about 6 P.M. a steamer flying

English colors, and having every appearance of one of her Britannic majesty's gunboats, approached the bar, and was met by our vessels under way; the "Oneida" fired three shots across the stranger's bow, the last at her fore-foot, without bringing her to; and then, within three minutes of the first gun, fired a broadside into her, and continued the chase, with the other vessels, until she, from her superior speed, was enabled to run in over the southeast shoals under cover of Fort Morgan's guns. This steamer proved to be the rebel cruiser "Oreto," afterwards called the "Florida." Her commander subsequently wrote as follows:

"I can vouch for his (Preble's) promptness and destructive energy on the occasion of my entering Mobile Bay. The superior speed of the 'Florida' alone saved her from destruction, though not from a frightful mauling. We were torn to pieces,—one man's head taken off, and 11 wounded; boats, standing- and running-rigging shot away, also foregaff. Four shells struck our hull, and had the one (11-inch) that grazed our boiler and entered the berth-deck (killing one and wounding two) exploded, every man belonging to the steamer would have been killed, as I had only the officers on deck, until about to cross the bar, when I made some sail, and one man was wounded in the rigging; we had about 1400 shrapnel-shot (balls) in our hull, and our masts were pitted like a case of smallpox. The damage done her was so great that we did not get to sea again for over three months."

For not preventing the "Oreto's" running the blockade, Commander Preble was summarily dismissed from the naval service, by order of September 20, 1862, but was nominated to the Senate by the President, and on recommendation of the Naval Committee was, on February 21, 1863, confirmed and restored to his proper rank and position as a commander, the injustice of his summary dismissal being generally admitted. April 9, 1863, agreeably to orders from the Navy Department, proceeded *via* England to Lisbon, and June 3 took command of the sailing-sloop "St. Louis" at the latter port, and ordered to cruise for rebel corsairs between Lisbon, the Azores, Canary Islands, and Gibraltar. Though requesting more active duty, and command of a steamer on the coast, he was in command of the "St. Louis," cruising within those limits, until ordered to Port Royal, S. C., September 3, 1864, once falling in with his old foe, the "Florida," at Madeira, and preventing her from getting a full supply of coal, but not able to prevent her from running out in a calm. He gave chase as soon as he got wind, but of course did not catch her.

Reported to the admiral November 2, 1864; took charge of the coal depot, and blockaded in the North Edisto until November 24, when he was ordered to command the fleet brigade then organized by Admiral Dahlgren at Port Royal, to co-operate with an army force designed to assist Gen. Sherman's approach to the coast; this brigade, consisting of naval artillery, sailor infantry, and a marine battalion, 493 all told, joined an army force under Gen. J. P. Hatch at Boyd's Neck, and on November 30, 1864, engaged in the severe battle of Honey Hill; it also took part in the actions of the 6th, 7th, and 9th of December on De Vaux's Neck, and was daily under fire until withdrawn on December 28; the general orders and written commendations of Rear-Admiral Dahlgren and Gens. Foster, Hatch, and Porter, were gratifying to all connected with the brigade (see Secretary of Navy's Report, 1865); April 4, transferred to the command of the steamer "State of Georgia," and proceeded to Aspinwall to look after American interests; his vessel and the "Huntsville" rescued 600 or 700 passengers from the wrecked steamship "Golden Rule," near Aspinwall; in acknowledgment of this service he received the thanks of the rescued people, transmitted through the Navy Department; the "State of Georgia" returned to New York, and went out of commission September 11, 1865. At Boston Navy-Yard as general inspector of supplies, from October 14, 1865, to July 5, 1867, and continued as equipment-officer until July, 1868; chief-of-staff, North Pacific Squadron, from August, 1868, until December 19; commanding the flag-ship "Pensacola," 1868–70.

Commissioned as captain, March 16, 1867, to take rank from January 29, 1867; commanding naval rendezvous, Boston, 1871–72.

Commissioned as commodore, November 2, 1871; commanding navy-yard, Philadelphia, 1873–75; special duty, 1876.

Commissioned as rear-admiral, September 30, 1876; commanding South Pacific Station, 1877–78. Retired February 25, 1878.

Precession of the Equinoxes. The equinoctial points have a backward movement along the ecliptic of about 50″ annually, caused by the unequal attraction of the sun and moon on the equatorial belt. The number of seconds in the zodiac divided by the annual motion of the equinox gives the time in which it will make the entire circuit of the ecliptic; it is about 25,870 years. From a similar computation it is supposed that the zodiac was divided into signs about 2500 B.C. See EQUINOXES, ZODIAC.

Preparing for Sea. The performance of certain duties previous to leaving port, by which the vessel will be rendered efficient, and additional security given to the equipment and outfit.

These duties are connected with all of the different departments of the vessel. The preparations to be made may vary under different circumstances, but the following requirements should be generally observed.

Provisions in sufficient quantity should be on board and properly stowed. Fill water-tanks and casks with fresh water, unless that is to be done by distillation after leaving port. If a steam-vessel, have a sufficient supply of coal on board, have fires ready for lighting, and hoist the smoke-stack.

The battery must be secured for sea with extra tackles and lashings, the muzzle-bags put on and the ports closed. Bend sails and all sail-gear, take off sail-covers, and have everything in readiness for making or shortening sail.

Put on chafing-gear. Cross light yards, or place them in the rigging ready for sending aloft. Send up rolling and pendent tackles, if required, and have storm-sails and their gear easy of access. Hoist all boats and secure them. Life-boats must be kept in readiness for lowering at a moment's notice.

Take in accommodation-ladders. Secure lower booms alongside, unhooking the topping-lifts and stopping them on the fore-yard. Top the

spanker-boom up clear of the crotch, and see that the life-buoys are in order.

Hand lead-lines must be placed in the chains, and the deep-sea lead and line should be ready for use. Log-lines and time-glasses should be measured and compared to insure their correctness, and the wheel-ropes and tiller examined, that they may be in working order.

Loose articles on all the decks should be securely lashed. Close lower-deck air-ports, and, previous to getting under way, take the vessel's draft.

Preparations must also be made for getting under way. Reeve the cat- and fish-falls, bring the chain to, and rig the capstan.

In all ports where quarantine regulations are enforced, care must be taken to have a bill of health, certified by the proper authority.—*E. T. Strong, Lieutenant U.S.N.*

Press-gang (*Eng.*). A party of seamen who (under the command of a lieutenant) were formerly empowered, in time of war, to take seafaring men—on shore or afloat—and compel them to serve on board men-of-war. Those who were thus taken were called *pressed men.* See IMPRESSMENT.

Press of Sail. As much sail as the state of the wind and sea will permit a ship to carry.

Pressure-gauge. An apparatus to indicate the pressure of fluids; there are many different kinds, and they may be divided into two principal classes: *first*, those which act by the effect of pressure (either direct, or transmitted by pistons, or elastic diaphragms) on a column of mercury; and, *second*, those which depend for their action upon the elasticity of metals, in which the pressure acts against a corrugated plate, within a corrugated box, in resisting a spiral spring, or in tending to straighten a bent tube, the cross-section of which is usually elliptical, but may be any form except circular.

Preston, Samuel N., and Porter, Benjamin H., Lieutenants U.S.N. Samuel N. Preston was appointed to the Naval Academy from the State of Illinois in October, 1858. Being a diligent student, he always stood foremost in his studies, and, graduating first in his class, he was on the 9th of May, 1861, detached and assigned to duty on board of the U. S. S. "Wabash," in the South Atlantic Blockading Squadron, being on the 1st of August, 1862, promoted to the grade of lieutenant, and ordered to duty as flag-lieutenant on the staff of Rear-Admiral Dahlgren.

He participated with distinction in the combined army and navy attacks on Fort Wagner, July 10 and 11, 1863, being complimented highly by the admiral for his gallant conduct.

He commanded the third division of the assaulting-party in the attempt on Fort Sumter, September 8, 1863, which was repulsed with great slaughter, and he, with many other officers,—among them his friend Benjamin H. Porter,—was taken prisoner and afterwards confined in Libby Prison, where he remained until exchanged, in the fall of 1864.

Benjamin H. Porter was appointed to the Naval Academy from the State of New York on November 29, 1859, and remained a student there until November 8, 1862, when he was commissioned ensign and ordered to duty in the South Atlantic Blockading Squadron, serving in turn with great credit on board of the U. S. S. "Ellis," "Canandaigua," and "New Ironsides," displaying on numerous occasions such energy, courage, and ability in the discharge of his duties as to win the admiration of his commanding officers and compliments from the admiral in his communications to the Department.

In the attack on Fort Sumter on the 8th of September, 1863, he was among those who were taken prisoners, remaining in Libby Prison until released and exchanged, in the fall of 1864.

Both of these gallant young officers, as soon as they were free, applied for immediate active duty, and in December, 1864, were assigned to duty under Rear-Admiral David D. Porter; Lieut. Preston being made his flag-lieutenant, and Lieut. Porter being given the command of the flag-ship "Malvern." They were present in the bombardments of Fort Fisher on the 24th and 25th of December, 1864, and in the land attack on that fort made by the sailors from the fleet both were assigned to duty of great responsibility, and fell nobly at the head of their men in the gallant discharge of that duty.

Side by side these young officers went through their careers. Together they were students at the Naval Academy; they served in the same squadron, were fellow-prisoners amid the horrors of Libby Prison, and together they fell gloriously at Fort Fisher,—fine types of able, zealous, and brave officers.

A fitting tribute was paid them by Fleet-Capt. K. R. Breese, who, in reporting their loss, says:

"Preston, after accomplishing most splendidly the work assigned him by you, which was both dangerous and laborious, under constant fire, came to me as my aid for orders, showing no flagging of spirit or body, and returning from the rear, whither he had been sent, fell among the foremost at the front, as he had lived, the embodiment of a United States naval officer. Porter, conspicuous by his figure and uniform, as well as by his great gallantry, claimed the right to lead the headmost column with the 'Malvern's' men he had taken with him, carrying your flag, fell at its very head.

"Two more noble spirits the world never saw, nor had the navy two more intrepid men. Young, talented, and handsome, the bravest of the brave, pure in their lives, surely their names deserve something more than a passing mention, and all worthy to be handed down to posterity with the greatest and best of naval heroes."—*F. P. B. Sands.*

Preventer. A term applied to ropes, etc., when used as additional securities to aid other ropes in supporting spars, etc., during a strong gale; as preventer-backstays, braces, etc.

PREVENTER-BOLTS. Bolts passing through the lower end of the preventer-plates.

PREVENTER-PLATES. Short plates of iron bolted to the lower part of the chain-plates to help take the strain.

Price, Cicero, Commodore U.S.N. Born in Kentucky. Appointed midshipman from that State, February 1, 1826; frigate "Macedonian," Brazil, 1826–28; sloops "Erie" and "Shark," West Indies, 1829–31.

Promoted to passed midshipman, April 28, 1832; brig "Boxer," 1834–37, and "North Carolina," 1837–38, Pacific Squadron.

Commissioned as lieutenant, September 6,

1837; steamer "Fulton," Atlantic coast, 1840; in "Delaware," 74, Brazil and Mediterranean, 1841–43 and part of 1844; receiving-ship at New York, 1845; sloop "Marion," coast of Africa, 1846; sloop "Marion," Mediterranean, 1848–49; navy-yard, Memphis, 1850; Pacific Squadron, 1851; ordnance duty, 1853; receiving-ship at Norfolk, 1854.

Commissioned as commander, September 14, 1855; first lieutenant of sloop "Constellation," Mediterranean, 1855–56; commanding "Huntsville," 1861.

Commissioned as captain, July 16, 1862; commanding sloop "Jamestown," East Indies, 1862–65.

Commissioned as commodore, September 28, 1866. Total sea service, 21 years and 1 month; shore or other duty, 6 years and 1 month. Retired December 2, 1867.

Pricker. A small fid or marling-spike for making and stretching the holes for points and robans in sails.

Pricking a Sail. Middle-stitching the seams of old sails, or of storm-sails.

Pride of the Morning. A misty dew at sunrise; a light shower; the end of the land breeze followed by a dead calm in the tropics.

Primary Planet. See PLANET.

Prime. To carry water with the steam from the boiler to the cylinder of a steam-engine; caused by insufficient steam room in the boiler, resulting in the pressure being reduced below that due to the temperature, by dirty feed-water, and by running from salt water into fresh, which boils at a lower temperature.

To get a gun ready for firing by pricking the cartridge and inserting the primer. In firing salutes, the vent is sometimes partly filled with loose powder to insure instantaneous ignition. *To prime a fire-ship*, to lay the train to set it on fire.

PRIMER. Percussion- and friction-primers are generally in use, though electric primers may be used in special cases. The *percussion-primer* consists of a quill tube filled with grained powder, and surmounted by a wafer-head containing a detonating composition of fulminating mercury and mealed powder. The lower end of the tube is closed by dipping it in black varnish, and the whole is coated with shellac. The *friction-primer* is a brass tube 1.5 inches in length and .19 inch in diameter, filled with fine-grained powder, and having near the head a small spur .44 inch long and .15 inch in diameter. In this spur is a brass wire, the inner end being flattened and having serrated edges. The composition in the spur is composed of two parts of sulphuret of antimony and one part of chlorate of potassa. The outer end of the wire is formed into a loop, into which the lock-string hooks. A longer tube is furnished for firing guns with very thick walls. The *quill* friction-primer consists of two quills, one within the other, the lower end being filled with fine-grained powder, and the upper with a sensitive composition composed of 55 parts of antimony trisulphide, 37 parts of potassium chlorate, 5 parts of flowers of sulphur, and 3 parts of gum arabic. In the composition are imbedded wires, which, upon being hauled out, cause the ignition. *Electric primers* are sometimes used in firing salutes, and may be used in firing in a seaway, the rolling of the ship closing the circuit when the deck forms a certain angle with the horizon. This automatic firing is, as yet, but a matter of experiment.

PRIMING-WIRE. A wire used in pricking the cartridge when it is home.

Prime Vertical. That vertical circle which passes through the east and west points of the horizon. Its poles are therefore the north and south points, and its plane is perpendicular not only to that of the horizon, but also to that of the meridian.

Primitive Plane (Lat. *primitīvus*, the first of a system). In projections the primitive plane is that on which the surface to be represented is delineated.

Prise. To raise, or slue, weighty bodies by means of a lever-purchase or power.

Prismatic Compass. A compass so fitted that, when a bearing is observed with it, the graduation of the card is read off by reflection from the interior surface of a prism. This prism is a solid piece of glass, whose sides are parallelograms and ends triangles.

Prisoner at Large. A prisoner not in irons or in confinement.

Prisoner of War. Such captured enemy as is protected by the state, or one in whom the captor claims a right of property and ransom. Before the 16th century they were treated as pirates. See PAROLE.

Prison-ship. One fitted up for receiving and detaining prisoners of war.

Pritch. A dentated weapon for striking and holding eels

Privateer. A private armed vessel, commissioned by the government in time of war, to prey upon the commerce of the enemy.

In ancient Rome, in the time of Cato and Cicero, it was held that no one but a regularly enrolled soldier could lawfully kill an enemy; but later, the law of Solon, by which individuals were permitted to associate themselves for the purpose of plundering enemies, was adopted by the Romans, and has been in effect transmitted to our times. No commission for such a purpose was necessary until the 15th century, nor did the practice of granting commissions to privateers become general till the war between Spain and the revolted Netherlands, at the end of the 16th century. The question whether a commission is necessary to give to private armed cruisers, in time of war, the character and immunities of lawful combatants has been much discussed, and in the United States the doctrine of the law of nations is considered to be, "that private citizens cannot acquire a title to hostile property, unless seized under a commission, but they may still seize hostile property in their own defense. If they depredate upon the enemy without a commission they act upon their peril, and are liable to be punished by their own sovereign; but the enemy is not warranted to consider them as criminals, and, as respects the enemy, they violate no rights by capture." It may be said, however, that the present state of sentiment among enlightened nations would render the practical application of this doctrine highly dangerous, and that hostilities on the part of a cruiser without commission would doubtless expose the offending party to the most rigorous treatment. At the Congress of Paris (1856) the plenipotentiaries of Great Britain, Austria, France, Russia, Prus-

sia, Sardinia, and Turkey united in a declaration that "privateering is and remains abolished." The United States, however, has never assented to this declaration, and as to it, therefore, privateering remains legitimate. See INTERNATIONAL LAW, 10; PARIS, DECLARATION OF.

PRIVATEERSMAN. One of the crew of a privateer.

Private Signal. A signal intelligible only to those having the key.

Prize. A captured vessel or other property taken in naval warfare. The right to all captures vests primarily in the sovereign, and no individual can have any interest in a capture by a public or private vessel except what he receives under the grant of the state. See INTERNATIONAL LAW, 11.

PRIZE-COURT. The court whose jurisdiction includes the adjudication and disposition of prizes. See INTERNATIONAL LAW, 12.

PRIZE-GOODS. Those taken upon the high seas —*jure belli*—from the enemy.

PRIZE-LIST. A return of all the persons on board, whether belonging to the ship or supernumeraries, at the time a capture is made; those who may be absent on duty are included.

PRIZE-MASTER. The officer to whom a prize is given in charge to carry her into port.

PRIZE-MONEY. Proceeds of the sale of captures made as prize by authority of the United States. Vessels and their cargoes captured as prize must be sent into port for an adjudication in a prize-court in the manner prescribed by law. If condemned, the property is sold by the U. S. marshal, and the proceeds, when the capture was by a vessel or vessels of the navy, disposed of according to the decree of the court. If the prize was of equal or superior force to the vessel or vessels making the capture, the whole of the net proceeds will be decreed to the captors; and when of inferior force, one-half will be decreed to the United States and the other half to the captors. The prize-money adjudged to captors is distributed in the following proportions:

First. To the commander of a fleet or squadron, one-twentieth part of all prize-money awarded to any vessel or vessels under his immediate command.

Second. To the commander of a division of a fleet or squadron, on duty under the orders of the commander-in-chief of such fleet or squadron, a sum equal to one-fiftieth of any prize-money awarded to a vessel of the division under his command, to be paid from the moiety due the United States, if there be such moiety; if not, from the amount awarded to the captors. This fiftieth part is not awarded in addition to the share he would be entitled to as commander of a single ship making a capture, and he may elect which he will receive.

Third. To the fleet-captain, one-hundredth part of all prize-money awarded to any vessel of the fleet in which he is serving, except where the capture is made by the vessel on board of which he is serving, in which case he will share, in proportion to his pay, with the other officers and men on board such vessel.

Fourth. To the commander of a single vessel, one-tenth of all the prize-money awarded to the vessel, if such vessel at the time of the capture was under the command of the commanding officer of a fleet or a division, and three-twentieths if his vessel was acting independently of such superior officer.

Fifth. After the foregoing deductions, the residue is distributed among all others doing duty on board, and borne upon the books of the ship, including the fleet-captain, in proportion to their respective rates of pay.

All vessels of the navy within signal-distance of the vessel making the capture, and in such condition as to be able to render effective aid if required, will share in the prize. Any person temporarily absent from his vessel may share in captures made during his absence. The prize-court determines what vessels shall share in a prize, and also whether the prize was of superior, equal, or inferior force to the vessel or vessels of the captors. The Secretary of the Navy determines what persons are entitled to share in the prize-money awarded a vessel, and transmits their names to the Fourth Auditor, who ascertains, according to the above rules of distribution, the correct amount of each person's share. On application the Auditor will issue a certificate payable to the person entitled, provided Congress has authorized the payment by an appropriation. See BOUNTY FOR DESTRUCTION OF ENEMY'S VESSELS.

The share of prize-money awarded to the United States is set apart forever as a fund for the payment of pensions to naval officers, seamen, and marines entitled to pensions; and, if more than sufficient for that purpose, the surplus is applied to the making provision for the comfort of disabled officers, seamen, and marines. The Secretary of the Navy is trustee of the naval pension fund, and the fund is invested in securities of the United States bearing 3 per cent. interest. See NAVY PENSION FUND.

Privateers, and vessels not in the navy, but controlled by other executive departments of the government, do not come within the above provisions, but are entitled to prize-money under laws relating especially to themselves.

Proa. See FLYING PROA.

Probation. The novitiate period of cadets.

Procyon (Gr. *prokuōn;* from *pro*, before; *kuōn*, a dog, so called from its rising before Sirius). The proper name for the bright star *α Canis Minoris.* It makes an equilateral triangle with Sirius and Betelguese. See CANIS MINOR.

Professors of Mathematics. These officers were first appointed in the U. S. navy in 1831, for the purpose of instructing midshipmen on board ship, but such instruction has been found unprofitable, and latterly no professors of mathematics have been employed at sea. A limited number have been continued on the list at the Naval Academy and Naval Observatory. The first to receive the appointment was Prof. Elisha Fitch, September 25, 1831, who died October 15, 1839. At the present time there are 12 professors of mathematics in the navy on the active list, 3 having the relative rank of captain, 4 that of commander, 5 of lieutenant, and on the retired list 1 with rank of commodore, 3 of captain, and 2 of commander.

Projectiles. A projectile is properly, from its derivation, anything that is thrown forward, and may therefore not only refer to missiles to be employed against an enemy, but, as well, to signals of danger in peace times, or to the means employed to carry a line to the crew of a stranded

or sinking ship. In this article it will be treated in its former significance.

The first projectiles used were stones thrown from slings (afterwards lead bullets were projected in the same way), arrows from the long bow, and darts and javelins thrown by hand. In the sieges of walled towns, in very early days, ballistæ and catapults were used as a species of heavy ordnance, the former to hurl large stones, and the latter, wooden beams shod with iron and often covered with inflammable material previously ignited. But the projectile, as it is understood in modern times, came in with the use of gunpowder in warfare, and developed with the improvements in weapons using it. While lead answered all the purposes in small-arms, it was found too soft for battering with larger guns, and stone shot being not only too light for good flight, but also deficient in tenacity, early gave way to iron, which excelled in these qualities. Iron projectiles came into general use in Europe by the close of the 14th century, and by the middle of the succeeding century, grenades and explosive shells were introduced. The first ones are said to have been made of alloys of lead and tin and of bronze, but later they gave way to cast iron, and in many cases were of extraordinary size, reaching in Germany and Italy, towards the close of the 17th century, to 1100 and 1300 pounds weight. These shell were projected from mortars, and it was not until early in this century that shell-guns came into use, first in this country and afterwards in Europe. From this time up to the advent of rifle-guns, projectiles for heavy ordnance were not materially changed, except that they grew in size with the increasing calibre of the guns, were cast more carefully and by better methods, and the effect of the shell was heightened by improvements in the fuzes.

In smooth-bore guns, besides solid shot and shell, several other projectiles are used, such as "case-shot," which comprise "grape" for spreading a large number of balls at short range, "canister" for longer distances, and "shrapnel," which are thin shell containing small balls, and with a bursting charge just sufficient to rupture the shell. Other types of projectiles for smooth-bore guns are now obsolete in our service, such as chain- and bar-shot for cutting an enemy's spars, sails, and rigging, and hot shot and carcasses for setting him on fire, although the latter might be used with good effect on shore, and several European governments retain them, as well as "ground" and "parachute light-balls," to light up an enemy's works at night, and "smoke-balls" to appeal to his nose. Many of these projectiles had prototypes in the hot clay, hot iron, Greek fire, and stink-pots of the ancients.

The first rifled motion was given to spherical lead bullets fired from small-arms about the close of the 15th century, but the practice seems to have soon fallen into disuse, to obtain again nearly 200 years afterwards, and we have records of the good effects produced by the rifle in our Revolution. Several improvements in rifling and loading were introduced early in this century, and finally led up to the elongated bullet having a conical head, the rammer-head being recessed to prevent flattening out the point in loading. The Minié bullet was introduced in 1847. This is a cylindrical body with a conical head, and at the base is an iron thimble which, driving in at discharge, wedges the lead out into the grooves of the rifle. But it was soon discovered that a concave surface at the rear face of the bullet did quite as well as the thimble, which in some cases was driven through the bullet. The present service bullet has a concave base, and 3 grooves in a transverse plane at the forward end of the cylinder. They are made of an alloy of 16 parts lead to 1 of tin, are punched out in steel dies, and for the .45 calibre are of the following dimensions, in inches: Total length, 1.11; diameter of cylindrical part, .458; maximum diameter of conical part, .445; depth of grooves, .03; width of grooves, .125; width of lands, .083; weight in grains, 405. Experiments have lately been made with a bullet of 500 grains, using the same charge of powder (70 grains); and while the initial velocity has been less, the range has been increased, with a flatter flight during the falling part of the trajectory.

The rifling of heavy ordnance is of very recent date, for although Benjamin Robins, as early as 1742, foresaw its advantages and those of the elongated projectile, and while there are crude specimens preserved in the museums of some European countries, which date back still farther, it was not until 1854, before Sebastopol, and again in 1859, in the Italian campaign, that rifled cannon were employed with good effect. The war of secession soon following, and the use of armor for the protection of fighting ships, stimulated invention in ordnance to a great degree, and rang the death-knell of smooth-bore guns and spherical projectiles. Notwithstanding the immense amount of thought and study that has been expended on the subject of rifled guns and their projectiles, the question is far from being settled, and of the many systems proposed and in use, each has its warm advocates. The flight of an elongated projectile depends primarily upon its taking the rifled motion, and the steadiness with which it retains it about its longer axis. The devices for rotating the projectile are many, and their success depends mainly on the strength of the gun, the strength of the projectile, and the action of the powder-gases. A comparatively weak gun, with a good system of rifling and of projectiles, will stand where a much stronger gun may be burst by undue strains put upon it by a bad system. The devices now used for securing the rifled motion may be classed under three heads, viz., studded or flanged, forced or lead-coated, and expanding. Studded projectiles have buttons or flanges which follow corresponding grooves in the gun, as in the Woolwich and Armstrong muzzle-loaders. Forced projectiles are used in breech-loaders only, and are coated with lead or other soft substance to a size larger than the bore of the gun. Examples are shell and shrapnel for the 3-inch breech-loading navy howitzer, and projectiles for Krupp and Armstrong breech-loaders. Expanding projectiles are those where the action of the powder-gases expand into the grooves of the gun a soft rear band, as in the Parrott, Butler, Stafford, and Blakely systems, or a lead zone is forced out by a cap-wedge driven up from the rear, as in the Hotchkiss, or a papier-maché base is driven up on the shot, as in the Schenkl.

The object to be attained is, with the least

strain on the gun, to get a steady, uniform motion without balloting or wedging in the bore, no stripping, uniformity of range and velocities, and a steady flight. Besides these qualities a shell should have large capacity for a bursting charge, and all projectiles should be free from liability to injury in ordinary handling or transportation. Precautions should be taken in cleaning, filling, and fuzing shell to prevent premature explosions. Shell are generally made of cast iron and fuzed at the point. Battering shell are cast with a chilled head and not fuzed, while the walls are much thicker, the bursting of the shell being effected by the heat generated by impact against armor. Steel projectiles are now being made abroad, and used against armor shields with excellent results. At the recent Meppen experiments they excelled all others.

During the war many kinds of shell of each system were used, including not only inventions of our own citizens, but some purchased from other countries. The greatest number of shell used on the Northern side were Parrott, Hotchkiss, and Schenkl. That our ordnance officers, after much experience, should have adopted the expanding system with base rotation in all muzzle-loading guns argues strongly in its favor. Our breech-loaders are few, but in the navy, Parrott shell are used in them, with the exception of the 8-inch breech-loading howitzer, and in recent firing with the 9-inch breech-loading rifle, Butler shell were used.—*H. W. Lyon, Lieutenant U.S.N.*

Projection (Lat. *projectio*, a throwing out or stretching forth). A delineation of a proposed figure on a given surface, formed by means of lines drawn according to some definite laws. The projection of a surface is generally conceived as made by straight lines, and on a plane. This plane is called the *primitive plane*. A distinction is also drawn between *natural* and *artificial* projections. A *natural projection* of a surface on a given plane is such a delineation of it as would be formed by drawing straight lines from the eye in a definite position through every point of the surface to meet the plane, the original and the representation producing the same effect on the organ of vision. An *artificial projection* is a delineation of the surface on a plane traced according to fixed laws, not being a perspective representation.

Projections of the Sphere. Delineations of the surface of the sphere on a plane made according to definite laws, and furnishing the means of constructing maps and charts. Projections of the sphere are either *natural* or *artificial*. Natural projections of the sphere are delineations of the surface on a plane, defined in position, representing the sphere as it appears to the eye situated at a given point. According to the relative positions of the sphere, the eye, and the primitive or plane of projection, there are different methods of natural projection, the three most important of which are the *orthographic*, *stereographic*, and *central* or *gnomonic*. In the *orthographic* the eye is indefinitely distant from the sphere, so that the visual rays are parallel to one another, and the primitive is perpendicular to their direction; in the *stereographic* the eye is situated at the surface of the sphere, and the primitive passes through the centre so as to have the eye in its pole; in the *central* or *gnomonic* the eye is at the centre of the sphere, and the primitive is a tangent plane. Projections of the sphere, on whichsoever of the above methods they are made, are further named *equatorial*, *meridional*, or *horizontal*, according as the primitive coincides with or is parallel to the equator, the meridian, or the horizon. All perspective representations of the sphere distort those parts which are not projected near the centre of the primitive. Thus, in a map on the orthographic projection, countries at a distance from the centre of the primitive are unduly contracted, while the reverse is the case in maps on the central projection. In maps or charts of small portions of the earth's surface this is of little consequence, as the middle of the map may be always taken for the centre of the primitive; but for extensive tracts the distortion near the edge of the map is considerable, and constitutes an objection. Artificial projections of the sphere are delineations of the surface on a plane traced according to fixed laws, not being perspective representations. *Mercator's* chart, which is that of the greatest importance to the navigator, is an artificial projection. Here the meridians are parallel straight lines equidistant from each other, the parallels of latitude are perpendicular to the meridians at such distance from each other, increasing from the equator, that the measures of a degree of longitude and latitude at any point of the projection shall have the same ratio as exists between their measures on the surface of the sphere at the corresponding point. This projection gives a true representation as to *form* of every particular small tract, but varies greatly in point of *scale* in its different regions, the polar portions in particular being extravagantly enlarged, and the whole map even of a single hemisphere not being comprisable within any finite limits. See Chart.

Promiscui Usus. A law-term for those articles which are equally applicable to peace or war.

Promontory. A high point of land or rock projecting into a sea or lake, tapering into a neck inland, and the extremity of which, toward the water, is called a cape, or headland, as Gibraltar, Ceuta, Actium, etc.

Promotion. Promotions are made by seniority only, except in cases of extraordinary heroism. When an officer arrives at the head of his grade he must undergo examinations in regard to his physical and professional qualifications, and his record is consulted in respect of his moral character. See Examination, Board of.

Promovent (*Eng.*). The plaintiff in the instance-court of the admiralty.

Proof. The trial of arms, ammunition, etc., before being received for service.

Propeller. An instrument for propelling vessels. There are two principal kinds, the paddle-wheel and screw-propeller. The paddle-wheel may be worked by either horizontal or vertical shafts, and the paddles are either fixed or feathering. The action of the screw-propeller is that of a two or more threaded screw working in a nut, the water acting as the nut; but being a moving medium, the full benefit of the pitch is not obtained. See Paddle-wheel, Screw-propeller.

Proper Motion. See Motion, Proper.

Proportional Parts, Table of. An auxiliary table to facilitate the process of interpolation in the use of logarithms.

Prospect-glass. An old term for a spy-glass.

Protractor. An instrument for laying off angles in plotting.

Providence, R. I., the second city in population, wealth, and importance of the New England States, is situated around a little lake called the "Cove," into which two small rivers, the Woonasquatucket and Moshassuck, empty, and on Narragansett Bay, at the head of navigation. The Providence River, which flows out of the "Cove," is on the southeastern side of the city, and the Seekonk forms its eastern boundary. Providence was at one time the seat of a considerable foreign and domestic commerce, but of late years the foreign trade has considerably diminished, balanced, however, by an increase of the domestic trade. This city is one of the great manufacturing centres of the country. The most important establishments are those of the Gorham Company, manufacturers of solid silverware, the Providence Tool Company, Providence Steam-Engine Company, Barstow Stove Company, Allen Fire Supply Company, Fletcher Manufacturing Company, Corliss Steam-Engine Works, and many others, the total value of the manufactures according to the State census for 1875 being $52,000,000. Pop. 104,000.

Proviso. A stern-fast, or hawser, carried to the shore to steady by. A ship with one anchor down and a shore-fast is moored *a proviso*.

Provost-marshal. This term is applied in the navy to an officer who is charged with the safe-keeping of a prisoner while undergoing trial by court-martial. He does not arrest him, or execute the sentence of the court, as in armies, but receives him from the officer in whose custody he may be held, and is responsible for him in transit, and while before the court, and for his return when his presence is no longer required. The president of a general court-martial is authorized to order an officer of the navy not above the grade of lieutenant, or an officer of the marine corps not above the grade of captain, to serve as provost-marshal of the court. In addition to the above, it is his duty to serve notices to the witnesses, execute any process of the court, and attend generally as the police-officer of the court. He is not sworn, and receives no additional compensation. In the case of a trial of an appointed or enlisted man, the person to act as provost-marshal may, if the president of the court thinks proper, be a petty officer of the navy, or a non-commissioned officer of marines. It has not been the practice in the U. S. army for a provost-marshal to attend upon a military court.—*H. C. Cochrane, Captain U.S.M.C.*

Pucka. A word in frequent use among the English in the East Indies, signifying sterling, of good quality.

Pucker. A wrinkled seam in sail-making; also, anything in a state of confusion.

Puddening, or Pudding. A thick pad of yarns, matting, oakum, etc., tapering from the middle toward the ends; used for fenders on the bow of a boat. A covering of parceling and soft rope over the ring of the anchor when rope cables are used.

Pudding-fish. A fish of the genus *Sparus* (*S. radiatus*).

Puff. A sudden gust of wind.

Puffer. A fish of the genus *Diodon;* globe-fish. See GLOBE-FISH.

Puffin. The *Fratercula arctica*, a sea-bird with a singular bill, formerly supposed to be a bird in appearance but a fish in substance, in consequence of which notion the pope permitted its being eaten in Lent.

Pulas. An excellent twine, made by the Malays from the *kaluwi*, a species of nettle.

Pull. To row.

PULL-AWAY BOYS. A name given on the west coast of Africa to the native Kroomen, who are engaged by the shipping to row boats and do other work not suited to Europeans in that climate.

Pull Foot. To hasten; to run.

Pulo. The Malay word for island, and frequently met with in the islands of the Eastern seas.

Pulwar. A commodious kind of passage-boat on the Ganges.

Pump. A hydraulic machine for raising liquids. A machine for exhausting a gas from, or forcing a gas into, a close vessel. *To pump ship*, to pump the water out the bilge. A pump *sucks* when the water being exhausted, nothing but air comes up.

PUMP-BRAKE. A lever by which a pump is worked.

PUMP-DALE. A trough to carry off water from a pump; a hose is now used for this purpose.

PUMP-GEAR. The apparatus belonging to a pump.

PUMP-WELL. An inclosure around the bottom of the pumps to protect them from injury, and to give a ready admittance to the water, as well as to permit an examination into the condition of the pumps; it usually contains a strainer.

Punch. An iron implement for backing out a bolt, or for making apertures in metal.

Punishment. No punishment can be legally inflicted except by the commanding officer, or by the sentence of a summary or general court-martial.

Commanding officers are authorized to inflict the punishments of extra duties, deprivation of liberty, reduction of rating, and confinement with or without irons, either on full or reduced rations. The confinement must not exceed ten days. Flogging, gagging, and confinement in coal-bunker or sweat-box are forbidden, and no punishment not specially authorized by the regulations is tolerated. See COURT-MARTIAL.

Punk. The interior of an excrescence on the oak-tree; used as tinder, and better known as touch-wood.

Punt. An Anglo-Saxon term still in use for a flat-bottomed boat, used by fishermen, or for ballast lumps, etc.

Puoys. Spiked poles used in propelling barges.

Puppet-valve. See POPPET-VALVE.

Purchase. Any mechanical advantage which increases the force applied. See TACKLES.

PURCHASE-BLOCKS. All blocks virtually deserve this name, but it is distinctively given to those used in moving heavy weights.

PURCHASE-FALLS. The rope rove through purchase-blocks.

Purging-cock. A cock or valve in the lowest

part of a steam-boiler for the purpose of draining the boiler.

Purre. A name for the dunlin (*Tringa alpina*).

Purse-crab (*Birgus*). A genus of *Crustacea* of the order *Decapoda* and suborder *Anomoura.* It is allied to the Hermit Crab (which see), but has the abdomen or *tail* shorter and almost orbicular, its under surface soft and membranous, its upper surface covered with strong plates, overlapping, as in lobsters. The first pair of legs have large and powerful pincers, the pair nearest the abdomen are very small, but terminate in rudimentary pincers; the pair next to them are larger with small pincers; the second and third pairs of legs are terminated by a single nail.

Purse-net. A peculiar landing-net in fishing. It is used in the seine and trawl to bewilder the fish, and prevent their swimming out when fairly inside.

Purser. Falconer, in his Marine Dictionary, says, "A purser is an officer appointed by the Lords of the Admiralty to take charge of the provisions of a ship of war, and to see that they are carefully distributed to the officers and crew according to the instructions which he has received from the Commissioners of the Navy for that purpose."

Totten defines a purser in the U. S. navy as "a commissioned officer who has charge of the provisions, clothing, etc., and of the public moneys on board ship."

Sir Wm. Monson, about 1600, says, "The purser is in the nature of a cape-merchant in a ship of merchandise, that keeps an account of all things brought into the ship; he ought to be an able clerk." "Likewise if, during the voyage, any of the men happen to die or run away, or for good cause be discharged by the captain's order, to enter likewise the particular day of the month against each of their names in a margent of the books," etc.

The title was derived from *bursar*, the old name for a treasurer or cash-keeper; hence *disburser*, one who pays out money. The term *burse magister* existed in the English merchant marine in the time of Henry VI. The title remained in the U. S. navy from its organization until 1860. By a general order (1847), legalized by act of Congress, 1854, pursers of more than 12 years were to rank with commanders, and of less than 12 years with lieutenants, and to take rank with surgeons according to date of commission. In 1860 it was enacted "that pursers in the navy of the United States shall be hereafter styled 'paymasters.'" Why the old time-honored title was discontinued for a longer one, expressive of only a portion of this officer's duties, it is difficult to imagine. See PAY CORPS.

PURSER'S DIP. The smallest dip-candle.

PURSER'S GRINS. Sneers.

PURSER'S NAME. An assumed name.

PURSER'S POUND (*Eng.*). The weight formerly used in the navy, by which the purser retained an eighth for waste, and the men received only seven-eighths of what was supplied by government. One of the complaints of the mutiny was, having the purser's instead of an honest pound. This allowance was reduced to one-tenth.

PURSER'S SHIRT. *Like a purser's shirt on a hand-spike*, a comparison for clothes fitting loosely.

Purviance, Hugh Y., Commodore U.S.N. Born in Maryland. Appointed from Maryland, November 3, 1818; frigate "Congress," 1819–21, and "Franklin," 74, 1821–24, Pacific Squadron; "North Carolina," 74, Mediterranean Squadron, 1824–27.

Commissioned as lieutenant, March 3, 1827; sloop "Falmouth," West India Squadron, 1828–30; sloop "Peacock," East India Squadron, 1833–34; rendezvous, Baltimore, 1836–37; Brazil Squadron, 1837–38, commanding brig "Dolphin" and sloop "Fairfield"; relieved an American schooner from the French blockade at Salado, River Platte; rendezvous, Baltimore, 1839–40; "Brandywine," Mediterranean Squadron, 1841–42; rendezvous, Baltimore, 1843; commanding brig "Pioneer," coast of Africa, 1843; frigate "Constitution," Mexican blockade, 1846.

Commissioned as commander, March 7, 1849; receiving-ship "Consort," Baltimore, 1850–51; commanding sloop "Marion," coast of Africa, 1852–55.

Commissioned as captain, January 28, 1856; commanded frigate "St. Lawrence" on the blockade off Charleston and Southern coast, 1861; sunk the Confederate privateer "Petrel" off Charleston when just 12 hours out; captured several prizes; participated in the fight of the "Merrimac," gunboats, and batteries off Sewell's Point, Hampton Roads.

Commissioned as commodore, July 16, 1862; light-house inspector, 1863–65. Received a vote of thanks of Maryland Legislature. Retired December 21, 1861.

Push. To crowd all sail. To run the engines to their utmost capacity.

Put. *To put back*, to return to the point of departure. *To put about*, to go on the other tack. *To put to sea*, to quit a port or roadstead and go to sea.

Pyrosomidæ. A family of tunicated marine mollusks. They swim freely, many individuals being usually combined into a nearly cylindrical mass by means of their elastic integument, or *tunic.* They abound in warm seas, and are brightly luminous.

Pyroxylin. See EXPLOSIVES.

Q.

Q. In the log-book, *q* denotes *squalls*.

Quade. An old word for baffling ; as, a *quade* wind.

Quadrant. A quadrant (Lat. *quadrans*, a fourth part) is a reflecting astronomical instrument on the same principle as the sextant (see SEXTANT), but with a shorter arc, so that angles up to 90° only can be measured. If named on the same principle as the sextant it would be called an octant (Lat. *octans*, one-eighth), and this name has been given to the metal-framed quadrants made of late years. Quadrants have generally a wooden frame with an inlaid ivory arc, and were formerly made much larger than at present. The arc is generally divided to half-minutes only. See GUNNER'S QUADRANT.

Quadrature. The moon is in *quadrature* when she is 90° from the sun.

Quagmire. A marsh in which the water remains stagnant.

Quaker. A false or wooden gun.

Quamash, or Biscuit-root. A plant of the natural order *Liliaceæ*. The roasted bulbs are used as an article of food.

Quamino. A negro.

Quarantine (Ital. *quarantina ;* L. Lat. *quarentena ;* Fr. *quarantaine ;* Span. *cuarantena*). The Cyclopædia of Commerce defines quarantine to be the " interdiction of communication to which a ship is subject for a definite period, for fear of her bringing infectious diseases."

Webster defines the word as follows: "1. A space of 40 days. 2. Specifically, the term, originally of 40 days, but now of undetermined length, during which a ship, arriving in port, and suspected of being infected with a malignant, contagious disease, is obliged to forbear all intercourse with the shore ; hence, restraint or inhibition of intercourse to which a ship is subjected, on the presumption that she may be infected. 3 (*law*). The period of 40 days, during which the widow has the privilege of remaining in the mansion-house of which her husband died seized." "Quarantine (*verb*). To prohibit from intercourse with the shore ; to compel to remain at a distance, as a ship from shore when suspected of having contagious disease."

Falconer, in his dictionary, says, " Quarantine, the state of the persons who are restrained within the limits of a ship or lazaretto, or otherwise prevented from having a free communication with the inhabitants of any country till the expiration of an appointed time, during which they are repeatedly examined in regard to their health. It is chiefly intended to prevent the importation of the plague."

The term quarantine is now employed not only for the detention of persons, effects, and merchandise coming by sea, but also for such detention at international or state lines, or at a *cordon* arbitrarily drawn within a state. There is also a quarantine of observation imposed upon vessels that have, for any cause, communicated at sea with another from an infected port, or have been boarded by men-of-war of a hostile nation.

The original period of 40 days, or 6 weeks, imposed in early times, is supposed by some to have had a connection with the penitential period of lent; by others, that it was presumed that 6 weeks was the term or limitation in which any infectious disorder must certainly show itself. However this may be, the term is, and has long been established, in the senses given above, in the language of every sea-faring or mercantile nation.

In some countries vessels from the Levant, Barbary States, Havana, or Vera Cruz, have always to undergo some days' quarantine of observation, even when coming with clean bill of health. But modern experience has shown that some of the pestilential maladies, so called, are not contagious; and quarantine of *persons* has a constant tendency to become less severe, in northern climates especially; and a mere routine prohibition, like that just referred to, must eventually give way to more reasonable, liberal, and well-founded methods.

In 1852 a sanitary convention was held, most of the European states sending delegates, which body recognized the right of any country or countries to isolate another which was infected with plague, yellow fever, or cholera, either by sanitary cordon or by subjection to quarantine. By agreement two kinds of bills of health were recognized: one attesting the presence of disease in the country whence the vessel sailed, and the other attesting the absence of the malady. But vessels in bad sanitary condition, even if bearing the first-mentioned bill of health, were to be detained for purification whenever the authorities of the port at which she arrived deemed it necessary. The minimum of detention was agreed upon as follows: for vessels from countries suspected of plague, 10 full days ; 3 to 6 days for yellow fever, and 3 to 5 days for cholera. These terms are practically often exceeded, at the discretion of the health officers, especially in southern Europe. By the convention, merchandise was divided into 3 classes: 1st. That which is always quarantined and purified. 2d. That subject to detention and purification after examination and decision by experts. 3d. Those articles always exempt. Ships were to pay a health due according to tonnage ; and, while in quarantine, to pay a fixed daily rate, as must, also, persons placed in quarantine. Merchandise placed on shore at a lazaretto was to pay a special tax, by weight or valuation.

England refused to agree to this convention, and took the responsibility of practically doing away with quarantine in her ports for plague, yellow fever, and cholera, except under unusual

circumstances, when the power to enact quarantine lies in the crown, by an order in council. The orders in council in regard to yellow fever were revoked in 1869.

Although this is done there with impunity, at least as to the two first diseases, the wisdom of spasmodic action in regard to cholera may well be doubted. It would be impossible for countries situated in a lower latitude to follow her example. Nowhere, however, is quarantine more strictly enforced than in the British ports of Gibraltar and Malta; and the reason is that any attempt of the English government to alter the quarantine regulations of the Mediterranean colonies, without the sanction of the neighboring countries, would produce greater inconvenience than that arising from the present system. The *pratique* granted in those colonies would not then be recognized in the neighboring countries, and all vessels from Malta or Gibraltar would be subjected by them to a quarantine of observation.

In torrid countries, where yellow fever and cholera are endemic, quarantine is, of course, of little use, while in lat. 50° N. there is no fear of yellow fever. Large discretion must, however, in all cases and in all countries, be invested in the officers of health.

In 1865 another sanitary convention met at Constantinople, principally to deliberate in regard to cholera. This body again fully recognized the necessity of restrictive measures, while the importance of striking at the sources of epidemics in the places of their origin was duly set forth.

The importance of quarantine has been recognized from the earliest periods, although for ages it only consisted in the isolation of lepers. In the Middle Ages it was chiefly enforced against the plague, which had been the scourge of the Old World for so many centuries. We learn from history that the plague once prevailed at Athens, more or less severely, for 50 years. Hippocrates and Thucydides give accounts of it as far back as 330 B.C. The disease raged throughout the Roman empire from 250 to 265 of our era, and for some time 5000 persons died in Rome every day. When the plague appeared in Alexandria, A.D. 542, more than half the population was carried off. More modern instances of its dreadful ravages in Europe, Asia, and Africa are quite familiar, and it still prevails almost every year at Bagdad, and other places upon the Tigris and Euphrates.

In later days, in addition to plague, yellow fever, cholera, and typhus have been the diseases principally combated by quarantine, and for this purpose lazarettoes have been long in use. *Lazaretto* is derived from Lazarus, the patron saint of lepers. It may be defined as an isolated establishment, generally walled, on or near a port, built and arranged to receive the sick and those suspected of contagion, as well as merchandise. Lazarettoes are most common on the routes of commerce and travel on the shores of the Mediterranean. They often have extensive courts and gardens for air and exercise for those detained there, as well as appliances for disinfecting men, their clothing, and goods. The lazarettoes of Genoa, Leghorn, and Marseilles are so large and well arranged that ships need not necessarily be detained there, but may unload their cargoes in bond. Important papers, and money or letters necessary to be transmitted through quarantine, are still, in many cases, punctured, fumigated, or even immersed in weak acids before being allowed to circulate.

Although lazarettoes are of considerable antiquity, they were not established until, in the Middle Ages, the plague had repeatedly swept the great commercial cities of the Mediterranean, whence it spread to those of the interior with deplorable results, more than decimating many of them. At last the idea of protection was forced upon them, and Venice, as the queen of commerce, naturally took the lead. It has been said by some writers that there are traces in her records of some attempt at health regulations about 1130, and she certainly set the example of strict inspection of arriving vessels in 1318, while in 1403 the practice of isolation was introduced, the island of St. Mary of Nazareth being set apart for that purpose. Inspection of vessels was practiced at Reggio, in the Straits of Messina, almost at the same time as at Venice. Some accounts, indeed, state that Reggio preceded her. Count Barnabo, finding that those who avoided the sick generally escaped the plague, established a rough kind of quarantine, which consisted in placing those sick of the disease, found in vessels passing through the straits, in an open field, to die or to recover, and the persons engaged in handling the patients were excluded from communication with the population. In Florence the state took precautions against the spread of epidemics as early as 1348. In 1453 there was a lazaretto in Sardinia. In 1448 Venice had already a digest of quarantine laws, and in 1485 a regular health commission was established and the purification of cargoes begun.

The action of Venice, the centre of commerce, went far towards preventing the wholesale mortality which threatened to depopulate much of Europe, as the pest, once introduced, was fostered by the filthy and unwholesome mode of living then prevalent among all classes.

Genoa, always a rival of Venice, speedily followed her example as to quarantine, while at Marseilles, the third great commercial city of the Mediterranean, the first measures in this direction date from the plague of 1476.

These well-intended efforts were not always successful, for, in Marseilles, in 1656, it was not possible to bury the dead from plague, and they were obliged to be burnt, as has often happened elsewhere in sweeping epidemics. Marseilles, indeed, suffered from no less than 14 visitations of plague between 1505 and 1650. From the latter year, when more thorough precautions were taken, and a new lazaretto constructed, to 1720, she escaped entirely; and it has never again reached the city, although it has prevailed in the lazaretto twenty times, the last occasion being in the year 1825.

The annoying precautions necessary, and the time consumed by quarantine, have always varied with the locality, and the port from which the suspected or infected vessel came; and the severity of the rules, and the stringency with which they were insisted upon and carried out, have always excited the complaint of merchants and travelers. But as education and general intelligence extend, there is less and less disposition to question rules which commend themselves to every reasoning mind; and business in-

terests and sanitary requirements are now much more in accord. In all places it is a high misdemeanor to evade or break quarantine, and there appears less disposition to do this at the present day than formerly existed. McCulloch, in his Dictionary of Commerce, says, "In some cases, perhaps, quarantine regulations have been carried to a needless extent; but they have more frequently, we believe, been improperly relaxed."

As an instance of protection afforded by quarantine we may adduce the terrible scourge of yellow fever in Barcelona, in 1821, which was transmitted by sea, thence reached Marseilles, but was excluded from that city by rigorous quarantine. The instances of a like nature in our own country, both North and South, are too numerous to mention, especially in the epidemics of yellow fever in recent times.

Sanitary cordons, connected with the stamping out of foci of disease, have recently been eminently successful in preventing the spread of plague in Southern Russia, and of yellow fever in our Southwestern States.

A ship sailing from a port to one in another country is furnished by the consul of the country to which she belongs, or by the local authorities, with a bill of health, which shows the sanitary condition of the place of departure. If good, it is called a *clean* bill of health; and if, on the contrary, epidemic or contagious disease prevails, it is called a *foul* one. A bill from a suspected port is sometimes called a *touched* one.

The nature of the bill of health, and the declaration of the master of the vessel, regulate the length of quarantine, if any is required. It is not obligatory upon a master to take a bill of health, but the absence of one renders the vessel a suspected one in her port of arrival.

Pilots are everywhere required to make inquiry in regard to the port of departure and state of health of vessels which they may board, and are required to anchor them in proper place, accordingly, under heavy penalties. Fine and imprisonment are the usual penalties for gross invasion of quarantine law; and in France, under certain circumstances, the punishment may be death.

In the case of a man-of-war sailing from a port, the bill of health is usually furnished gratis by the authorities; and the declaration of the commander and of the medical officer is usually received as regards the state of health upon arrival.

Much the same precautions are taken with regard to the cattle plague as with merchandise and passengers, except that, in many instances, the animals are required to be killed at once, and always are sacrificed when symptoms of disease are shown.

In this country all vessels arriving from foreign ports, at any season of the year, must be boarded and examined by the officers of health, and coasting vessels come under the same category, according to the season of the year and the geographical position of the ports from which they come.

When a vessel and her passengers have leave to communicate freely with the shore, either directly upon arrival, or after having gone through a term of quarantine, she is said to have received *pratique.* This is derived from the Italian *pratica.* In the case of infected or suspected vessels, the crew and passengers, and their effects, are purified in the lazaretto or on board, and the hold of the vessel herself, and all cargoes of cotton, hemp, rags, paper, hides, skins, feathers, hair, and wool, are especially the objects of disinfection, while metals, lumber, sugar, live-stock, and other cargoes are treated as the discretion of the health officers may direct. In the Mediterranean all live animals, except horses, are supposed to be ready conveyors of plague, and cats more so than any others, as in Eastern countries they form part of households, which dogs do not.

On this continent the first quarantine law was enacted in the Province of Pennsylvania, in reference to yellow fever, in the year 1700. The quarantine station, still bearing the name of "Lazaretto," exists in the place in which it was originally established, a few miles below Philadelphia, and depuration of passengers and cargoes is still performed there.

The present condition of quarantine in the different States of the Union leaves much to be desired, as the States have different and sometimes conflicting laws. All provide some sort of quarantine for contagious and infectious diseases, but the practice in carrying out the necessary precautions is not uniform, and in many cases inefficient.

In 1804, Mr. Jefferson protested against the passage of a general law regulating quarantine, as an interference with States' rights; and each State has continued to have its own code, some very good, and others harassing and contradictory. A national quarantine law was proposed in 1872, but only passed one house of Congress. There is no doubt, however, that the passage of such an act is only a question of time.

The National Board of Health is now doing excellent service, not only in practical work, but in educating the people to a proper appreciation of the necessity of a general quarantine law. The following is the act of Congress establishing the National Board:

"AN ACT *to prevent the introduction of infectious or contagious diseases into the United States, and to establish a National Board of Health.*

"*Be it enacted by the Senate and House of Representatives of the United States of America, in Congress assembled,* That there shall be established a National Board of Health to consist of seven members, to be appointed by the President, by and with the advice and consent of the Senate, not more than one of whom shall be appointed from any one State, whose compensation, during the time when actually engaged in the performance of their duties under this act, shall be ten dollars per diem each and reasonable expenses, and of one medical officer of the army, one medical officer of the navy, one medical officer of the Marine Hospital Service, and one officer from the Department of Justice, to be detailed by the Secretaries of the several Departments and the Attorney-General respectively, and the officers so detailed shall receive no compensation. Said board shall meet in Washington within thirty days after the passage of this act, and in Washington or elsewhere from time to time upon notice from the president of the board, who is to be chosen by the members thereof, or upon its own adjournments, and shall frame all rules and regulations authorized or required by this act,

and shall make or cause to be made such special examinations and investigations at any place or places within the United States, or at foreign ports, as they may deem best to aid in the execution of this act and the promotion of its objects.

"SEC. 2. The duties of the National Board of Health shall be to obtain information upon all matters affecting the public health, to advise the several Departments of the government, the executives of the several States, and the commissioners of the District of Columbia on all questions submitted by them, or whenever, in the opinion of the board, such advice may tend to the preservation and improvement of the public health.

"SEC. 3. That the Board of Health, with the assistance of the Academy of Science, which is hereby requested and directed to co-operate with them for that purpose, shall report to Congress at its next session a full statement of its transactions, together with a plan for a national public health organization, which plan shall be prepared after consultation with the principal sanitary organizations and the sanitarians of the several States of the United States, special attention being given to the subject of quarantine, both maritime and inland, and especially as to regulations which should be established between State or local systems of quarantine and a national quarantine system.

"SEC. 4. The sum of $50,000, or so much thereof as may be necessary, is hereby appropriated to pay the salaries and expenses of said Board and carry out the purposes of this act.

"Approved March 3, 1879."

This act was supplemented by another, approved June 2, 1879, entitled "An act to prevent the introduction of contagious or infectious diseases into the United States."

This act provides for the co-operation of the National board with the State boards; and where there are no local boards, or their regulations and means of prevention are not sufficient, as is often the case, they are to be assisted by proper persons, to be detailed by the President; and if they shall fail or refuse to enforce proper rules and regulations, the President may detail proper persons to do so.

Rules and regulations shall be made by the National board by which information can be obtained of the sanitary condition of foreign ports from which contagious or infectious diseases are or may be imported into the United States. Consuls are obliged to make constant sanitary reports of the condition of such ports; and medical officers may be detailed for residence at such ports, for the purpose of giving advice and assistance, and for seeing that vessels sailing for the United States are put in good sanitary condition. Domestic reports are also obtained from all parts of the country, by which any tendency to the development of epidemics is at once detected. The sum of $500,000 provided by this act is to be disbursed under the direction of the Secretary of the Treasury, upon estimates made by the board, and the appropriation is considered continuous. Local sanitation, except in rare cases (where disinfectants and money to pay sanitary inspectors and police have been provided), is not one of the duties of the board, as no attainable appropriation would be sufficient to serve such a purpose.

This law was hardly promulgated when the board found itself confronted by an alarming outbreak of yellow fever in Memphis, as well as the occurrence of some threatening cases in New Orleans. The disease also appeared in some other localities, and the highest legal authorities recognized the obvious duty of the board to be the assistance of the local authorities in the stricken communities in their efforts to stamp out the disease and prevent its spread to other States. By the measures recommended by the board, and the pecuniary aid extended to enable the authorities to carry out the recommendations, the spread of the disease was actually restrained within narrow limits. Measures were also advised as to precautionary work during the succeeding winter, which proved so successful that a very hot summer has just passed without the occurrence of a single case of yellow fever in Memphis. This result is most encouraging. Space does not permit a reference to other functions of the National Board of Health; but we may say that the constant reports of experts received by it, with the publication of essays on drainage, ventilation, and cognate subjects, as well as the collection of statistics on a grand scale, have laid the foundation for a wise and scientific treatment of the whole subject of quarantine and national hygiene.

Another international conference upon quarantine is to be held at Washington in January, 1881.—*E. Shippen.*

QUARANTINE-FLAG. A yellow flag hoisted in a conspicuous place to indicate the presence of contagious disease. It is hoisted at the fore of vessels undergoing quarantine, and is familiarly termed *yellow-jack.*

Quarry. The prey taken by whalers,—a term borrowed from falconers.

Quarter. The part of a yard just outside the slings. The upper part of the topsides at the after end of a ship. *On the quarter*, the position of an object 45° abaft the beam.

QUARTER-BADGE. An artificial gallery; a carved ornament near the stern of those vessels which have no quarter-galleries.

QUARTER-BLOCKS. Blocks under the quarters of the yards, to act as leaders for the sheets and clewlines.

QUARTER-BOAT. Any boat is thus designated which is hung to davits over the ship's quarter; it is used as a life-boat.

QUARTER-DAVITS. Pieces of iron or timber with sheaves or blocks at their outer ends, projecting from a vessel's quarters, to hoist boats up to.

QUARTER-DECK. The upper deck abaft the mainmast. Naval etiquette requires all persons to salute on coming on the quarter-deck, and to conduct themselves in a decorous manner while thereon. The starboard side in port and the weather side at sea are reserved for the use of the commanding and executive-officers, and the officer of the deck.

QUARTER-DECKERS. Officers more conspicuous for their observance of etiquette than for their knowledge of the requirements of their profession.

QUARTER-DECKISH. Punctilious; severe.

QUARTER-FAST. See FAST.

QUARTER-GALLERIES. Projections from the quarters which are intended to ornament and make a finish to the quarters, as well as to be useful; they are only fitted on vessels of war.

QUARTERING. Wind blowing from a point about 45° abaft the beam.

QUARTER-TACKLE. A tackle hooked to the quarter of one of the lower yards, and used with the yard-tackle in hoisting heavy articles out or in. It has been superseded by the stay-tackle.

Quarter-galley. A Barbary cruiser.

Quarter-gunner. See GUNNER.

Quarter-hung. A gun is *quarter-hung* when the axis of the trunnions is below the axis of the bore.

Quarterly Returns. Returns of stores on hand at the end of the quarter, with the receipts and expenditures during the quarter.

QUARTER-MASTER. A petty officer who assists the navigator in the minor details of his various duties. The quarter-masters have charge of the log, leads, lights, colors, signal-apparatus, compasses, helm, etc., and in action are stationed at the conn, helm, and relieving-tackles, attend to making and reading signals, and when on soundings heave the lead. They keep regular watch from the beginning of a cruise till a ship goes out of commission. They are always selected from the most experienced and reliable seamen.

Quarters. The stations of officers and men at the guns for battle, for exercise, or for inspection. The stations for battle or for exercise, as though engaged in battle, are distinguished as *general quarters*. The apartment allotted to a person or mess.

QUARTER-BILL. A bill giving the stations of officers and men in actions.

Quarter-watch. A division of one-fourth part of the ship's company. In the days when a ship carried a large number of men, a quarter-watch was sufficient to handle her in pleasant weather.

Quashee. The familiar designation of a West India negro.

Quator Maria. The four seas which surround Great Britain; the British Seas.

Quay. An artificial bank or wharf, at the side of a harbor or stream, at which vessels receive and discharge cargo.

QUAYAGE. Wharfage.

QUAY-BERTH. A loading or discharging berth for a ship in a public dock.

Quebec, the second city of Canada, is situated on the left bank of the St. Lawrence River (which is here joined by the St. Charles), in lat. 46° 49′ 6″ N., and lon. 71° 13′ 45″ W. Shipbuilding is the principal industry. There are also manufactures of iron castings, machinery, cutlery, nails, leather, musical instruments, rope, etc. The principal export is lumber, furnished principally by the forests on the Ottawa and St. Maurice Rivers, and down these rivers it is rafted to the St. Lawrence, and the rafts sometimes extend for 6 miles along this river at Quebec. Pop. 55,000.

Quebranta Huesos (*Sp.*). Literally, *bone-breaker.* A name for the great petrel, *Procellaria gigantea.*

Queche. A small Portuguese smack.

Queen's Parade (*Eng.*). The quarter-deck.

Queenstown, Cork County, Ireland, is situated on the south side of Great Island, in Cork harbor. It is well protected by batteries, and on the islands opposite are additional fortifications, magazines, etc. American steamers bound for Liverpool usually call at Queenstown. Pop. 11,000.

Queriman. A mullet of Guiana, found in turbid waters.

Querquedule. A light vessel; a boat. Also, a sea-fish.

Quicken. In ship-building, to give anything a greater curve.

Quick Firing. See FIRING.

Quick-match. See MATCH.

Quick-saver. A span formerly used to prevent the courses from bellying too much when off the wind.

Quick-work. All that part of a ship which is under water when she is laden; it is also applied to that part of the inner upper-works of a ship above the covering-board. Also, the short planks worked inside between the ports. In ship-building the term strictly applies to that part of a vessel's side which is above the chain-wales and decks, as well as to the strakes which shut in between the spirketings and clamps. In general parlance quick-work is synonymous with *spirketing.*

Quietus. A severe blow; a settler.

Quill-tube. See PRIMER.

Quilting. A kind of coating formed of sennit, strands of rope, etc., outside any vessel containing water. Also, the giving a man a beating with a rope's end.

Quink. A name for the golden-eyed duck, *Anas clangula.*

Quinquereme. An ancient vessel with 5 banks of oars. According to Polybius a quinquereme carried 300 seamen and 120 soldiers. See TRIREME.

Quod. Durance; prison.

Quoin. A wedge-shaped wooden implement. Before the introduction of elevating screws, quoins were used in elevating guns. *Chocking-quoins* are used under the trucks of a gun-carriage to prevent its running out or in.

Quota-men (*Eng.*). Men raised for the navy at great expense by Pitt's quota-bill, in 1795. They received bounties of from $100 to $300.

R.

R. Abbreviation for *are* in the U. S. General Service Signal Code. On the ship's books, R denotes *run* when placed against the name of a deserter. In the log-book *r* denotes *rainy*.

Rabanet, or Rabinet. A small, slender piece of ordnance, formerly used for ships' barricades. It had a 1-inch bore, and carried about a ½-pound ball.

Rabatment. The drawing of the real shape of the molding of the pieces in the frames in any required position.

Rabatt, Morocco, is situated on the south side of the Boo Regreb River, at its mouth, immediately opposite Sale. It has strong walls and batteries, a citadel and barracks. It has manufactures of pottery and carpets, an export trade in wool and corn, and considerable traffic. It was formerly the centre of the European trade with Morocco. Pop. 27,000.

Rabbet. A groove in a piece of timber, cut for the purpose of receiving another piece. On the stem, stern-post, and keel of wooden ships it is cut to receive the planking.

Race. When the tidal-wave passing along the coast is arrested in its course, the water, under certain conditions, attains a height which causes it to flow off obliquely; such a current is called a *race*. The canal by which water is conducted to and from a water-wheel.

Race-horse. A duck of the South Seas, thus named, says Cook, for "the great swiftness with which they run on the water."

Racine is situated on the west shore of Lake Michigan, at the mouth of Root River, in Racine County, Wis., and is the second city in the State in commerce and population. It has large grain-elevators, threshing-machine works, woolen-mills, wagon-factories, fanning-mill factories, wire-works, machine-shops, etc. Owing to its extensive manufacturing enterprises, Racine requires great shipping facilities, and these are supplied by three lines of railways. On the lake the West Shore Steamboat Line makes daily trips to Chicago, and the lower lake propellers make regular stops at this port. There are in addition to these quite a number of sailing-vessels owned here. Pop. 18,000.

Racing. A term applied when a marine engine suddenly acquires an abnormally high or irregular speed, caused by the propeller being partially emerged from the water by the action of a heavy sea.

Racing, Laws of Boat- (Adopted by the National Association of Amateur Oarsmen).

1. All boat-races shall be started in the following manner: The starter, on being satisfied that the competitors are ready, shall give the signal to start.

2. If the starter considers the start false, he shall at once recall the boats to their stations, and any boat refusing to start again shall be disqualified.

3. Any boat not at its post at the time specified shall be liable to be disqualified by the umpire.

4. The umpire may act as starter as he thinks fit; where he does not so act, the starter shall be subject to the control of the umpire.

5. Each boat shall keep its own water throughout the race, and any boat departing from its own water will do so at its peril.

6. A boat's own water is its straight course, parallel with those of the other competing boats, from the station assigned to it at the starting to the finish.

7. The umpire shall be sole judge of a boat's own water and proper course during the race.

8. No fouling whatever shall be allowed; the boat committing a foul shall be disqualified.

9. It shall be considered a foul when, after the race has commenced, any competitor, by his oar, boat, or person, comes in contact with the oar, boat, or person of another competitor, unless, in the opinion of the umpire, such contact is so slight as not to influence the race.

10. The umpire may, during a race, caution any competitor, when in danger of committing a foul.

11. The umpire, when appealed to, shall decide all questions as to a foul.

12. A claim of foul must be made to the judge or the umpire by the competitor himself before getting out of his boat.

13. In case of a foul, the umpire shall have the power—*a.* To place the boats (except the boat committing the foul, which is disqualified) in the order in which they come in. *b.* To order the boats engaged in the race, other than the boat committing the foul, to row over again on the same or another day. *c.* To restart the qualified boats from the place where the foul was committed.

14. Every boat shall abide by its accidents.

15. No boat shall be allowed to accompany a competitor for the purpose of directing his course or affording him other assistance. The boat receiving such direction or assistance shall be disqualified at the discretion of the umpire.

16. The jurisdiction of the umpire extends over the race and all matters connected with it, from the time the race is specified to start until its final termination, and his decision in all cases shall be final and without appeal.

17. Any competitor refusing to abide by the decision, or to follow the directions of the umpire, shall be disqualified.

18. Boats shall be started by their sterns, and shall have completed their course when the bows reach the finish.

19. In turning races, each competitor shall have a separate turning-stake, and shall turn from port to starboard. Any competitor may turn any stake other than his own, but does so at his peril.

20. The umpire, if he thinks proper, may reserve his decision, provided that in every case such decision be given on the day of the race.

Rack. To bind two parts of a rope or tackle together with spun-yarn, marline, etc. An iron support for shot at the waterways and around the hatches. A receptacle for the hauling part of the topsail halliards. The upper stratum of clouds. *Rack of the weather*, the direction in which the upper stratum of clouds is passing.

RACK-BAR. A billet of wood used for twisting the bight of a swifter round, in order to bind a raft firmly together.

RACKING. Spun-yarn or other stuff used to rack two parts of a rope together.

RACKING-TURNS. Turns taken alternately over and under the parts of a rope to be bound together.

RACK-RIDER. The name of the samlet in northern fisheries, so called because it generally appears in bad weather.

Rack and Pinion. An arrangement of toothed gearing by which motion is converted from rotative to rectilinear, or from rectilinear to rotative. The rack consists of a straight bar provided with projections or teeth; the pinion is a revolving piece having teeth to match those of the rack, and both parts are provided with suitable bearings or supports. If the pinion is fixed in position, the rack will slide in direction of its length; and if the rack is fixed, the centre of the pinion will move parallel to its face. The velocity-ratio between rectilinear and rotative motion depends upon the ratio between the radius of the pitch-line of the pinion and that of the circumference through which the rotative motion acts.

Rack-block. A range of sheaves cut in one piece of wood.

Raddle. To interlace; as in making boats' gripes and flat gaskets.

Radford, William, Rear-Admiral U.S.N. William Radford was born in Virginia. He was appointed from the State of Missouri, March 1, 1825; attached to Mediterranean Squadron, 1827–28; and to sloop-of-war "Erie," West India Squadron, 1830–31.

Promoted to passed midshipman, June 4, 1831; attached to sloop-of-war "John Adams," Mediterranean Squadron, 1835.

Promoted to lieutenant, February 9, 1837; attached to sloop-of-war "Warren," Pacific Squadron, 1845–47.

Lieut. Radford commanded the party that cut out the "Malokadel," a Mexican vessel of war, at Mazatlan, west coast of Mexico; attached to store-ship "Lexington," 1852–53.

Promoted to commander, September 14, 1855; commanding sloop-of-war "Dacotah," East India Squadron, 1860–61.

Commissioned as captain in 1862; commanding sloop-of-war "Cumberland" in 1861, and was on court-martial duty at Old Point when that ship was attacked by the ram "Merrimac," which had steamed down from Norfolk. Commander Radford made strenuous exertions to reach his ship before the fight was over, but arrived at Newport News just as the "Cumberland" was sinking.

Promoted to commodore, April 24, 1863; commanded frigate "New Ironsides," an ironclad division of Porter's squadron, at the two attacks upon Fort Fisher, in December, 1864, and January, 1865; commandant at Washington Navy-Yard, 1866–68.

Commissioned as rear-admiral in 1868; commanding European Squadron in 1869–70; special duty, Washington, 1871–72. Retired March 1, 1870.

Radiant. The point whence numbers of shooting-stars seem to diverge in star-showers.

Radius-bar, or Radius-rod. A bar or rod restrained to a fixed centre at one end, and guiding a movable body, in an arc, at the other; as, in Watts's parallel-motion.

Radus. A name for the constellation Eridanus.

Raft. A number of logs, planks, etc., firmly bound together. See LIFE-RAFTS.

RAFT-DOG. A flat piece of iron, each end of which is bent at right angles and pointed.

RAFT-PORT. A port cut in a vessel, forward or aft, near the water-line, for convenience in loading or unloading timber; a timber-port.

Rag-bolt. A bolt having its surface roughened by raising sharp prominences by cuts of a chisel, so that it may not be easily withdrawn from the wood into which it is driven.

Rail. The upper part of the bulwarks. Rods and stanchions across the ship at the break of the poop or forecastle. *Rails of the head*, curved pieces of timber extending from the bows on each side to the continuation of the ship's stem, to support the knee of the head.

Rain-cloud. See CLOUD.

Rains. Belts or zones of calms, where heavy rain prevails; they exist between the northeast and southeast trade-winds, changing their latitude several degrees, depending on the sun's declination. In India "the rains" come in with the southwest monsoon.

Raise. To increase the apparent elevation of an object by approaching it. A vessel is *raised upon* when she is heightened in her upper works. *To raise the wind*, to procure funds. *To raise a mouse*, to make a mouse on a stay. (See MOUSE.) The prize-fighters have adopted this expression, and mean by it to raise a lump on the face of the opponent.

RAISE-NET. A kind of staked net, so called from rising and falling with the tide.

Rake. The overhang of the stern, stem, or masts of a ship beyond a perpendicular with the keel. To fire at a ship from such a position, ahead or astern, that the projectiles range fore and aft the ship, sweeping the decks.

RAKING-FIRE. See FIRE.

RAKISH. Having a saucy appearance indicative of speed and dash.

Raleigh, Sir Walter, was born in 1552, at Hayes, County of Devonshire, England. In 1568 he was sent to Oxford as a commoner of Oriel College, but only remained there one year, going to France as a volunteer in an expedition in aid of the Huguenots. Some years later we find him serving in the Low Countries with the English force sent by Queen Elizabeth to assist the Dutch in their struggle against the Spaniards. Participating in the desire of his half-brother, Sir Humphrey Gilbert, to establish a colony on the eastern coast of America, this remarkable man accompanied the unfortunate expedition in 1579, but happily escaped Gilbert's fate and returned home. Fired with the idea of creating a

great colonial empire which should make England the equal of Spain, Walter Raleigh obtained a patent from Queen Elizabeth for the discovery and settlement of parts of the great transatlantic shore, and on the strength of this power he dispatched 2 vessels under Amades and Barlow, to proceed to the coast of Florida. The result was the possession and occupation of the territory called, in compliment to the maiden queen, Virginia. This occurred in 1585–86. Ten years later Raleigh obtained the means of proceeding to what he believed to be a land of gold,—El Dorado, in fanciful phrase,—but in reality the shore of the northeastern part of South America. He reached Guiana, and proclaimed it the property of England. Leaving his ships at the mouth of the Orinoco, he sailed 400 miles up the river, and succeeded in gaining the good will of the Indians. But beyond the honor of the geographical discovery Raleigh reaped no advantage from his voyage to Guiana, nor was the queen or her successor, James I., disposed to ratify the enterprise by formally colonizing Guiana. On his return home he fell into disfavor with James I., and for an imputed offense suffered 12 years' imprisonment in the Tower of London. After his release the king, to gratify his own cupidity, sanctioned a second voyage to Guiana. Its unproductiveness revived the animosity which had contributed to his long imprisonment, and being put upon his trial on new charges, he was sentenced to be beheaded, and on the morning of the 29th of October, 1618, in the 66th year of his age, he was executed.

Ram. A long spar, iron-hooped at the end, used for driving out blocks from beneath a vessel's keel, and for driving planks an-end while only wedged to the ship's side. *To ram*, to force home the charge of a gun. To run bows-on into another vessel. See Marine Rams.

Rammer. A staff with a cylindrical head, used in loading to press home the charge of a gun.

Rambade. The elevated platform built across the prow of a galley, for boarding, etc.

Ram-block. An old name for a dead-eye.

Ramed. Said of a ship upon the stocks when the frames, stem, and stern-post are adjusted from the use of the ram-line.

Ram-head. An old name for a halliard-block.

Ram-line. A small line which was used in old times for the purpose of determining the centre-line of a ship, and also for running sheer-lines when long battens were not attainable.

Ramper-eel. A name of the lamprey, *Petromyzon marinus.*

Ram-reel. Synonymous with *stag-dance.*

Ramsgate, Kent County, England, is situated on the east coast of the Isle of Thanet. Its artificial haven, formed by two stone piers projecting from 1500 to 2000 feet into the sea, incloses an inner basin, and is bordered by wet- and dry-docks. It is a member of the Cinque Port of Sandwich, and has quite a coasting-trade, fisheries, and imports of provisions from the Netherlands and France. Pop. 14,700.

Ran. Yarns coiled on a spun-yarn winch.

Rance. The strut or support of a Congreve-rocket.

Randan. A mode of rowing with alternate long and short oars.

Random Shot, or Random Range. A shot made when the muzzle is highly elevated; the utmost range may be at an angle of 45°, which is supposed to be about ten times as great as the point-blank, but improved gunnery has now put the term out of use.

Range. The straight line joining two prominent objects. The distance from the muzzle of a gun to the point at which the projectile first strikes. (See Point-blank.) *To range*, to sail parallel with and near to; as, *to range the coast, to range alongside*, etc. *Range of cable*, a certain quantity of slack cable hauled up out of the locker and ranged along the deck, to decrease the strain brought on the cable and bitts when the anchor is let go.

Range-heads. The windlass-bitts.

Rangoon, the capital of British Burmah and of Rangoon district, India, is situated on the east arm of the Irrawaddy, in lat. 16° 46′ N., lon. 96° 17′ E. It has a great trade in rice, cotton, petroleum, and teak timber. It is accessible to large ships, and also has an immense river traffic. Pop. 99,000.

Rank. A step or degree in a graduated scale of authority. In this sense it is synonymous with *grade*, but the conventional use of the two words *rank* and *grade* among naval and military men implies a distinction between them which is illustrated by saying that while there may be several individuals of the same grade, there can be but one of a given rank. In this narrow and conventional sense, therefore, rank may be defined as the expression of relative authority between individuals of the same grade. As an example of what is meant by this, the Navy Register contains the names of 50 officers in the *grade* of captain, but of all this number no two are of the same *rank.*

Actual rank is that held by an officer in his own corps. *Relative rank* is that given by law to officers acting as chiefs of bureaus, in cases where their actual rank is lower than that fixed by law as appropriate to the position, and to all staff officers, in order to assimilate their respective grades to those grades of the line which are deemed equivalent in dignity and importance. Relative rank, as between officers of the army and navy, is established by law, and is sometimes called *assimilated* rank.

Brevet rank does not exist in the navy, but in the army means rank in the army at large, and is conferred for gallant actions or meritorious services.

In another sense *rank* means a line or row of soldiers reckoning from side to side; *the ranks*, the body of common soldiers; *rank and file*, the general mass of enlisted men, privates and non-commissioned officers, excepting the non-commissioned staff. To *rank*, or to *take rank of*, is to be entitled to, or to have, precedence in matters involving the exercise of authority, or on occasions of ceremony.

Rank, Insignia of. Distinguishing marks established by law to be worn by officers of the army and navy, to indicate the grade of the wearer. In the navy the grade of officers is indicated by devices in the epaulet, shoulder-knot or strap, and by stripes of gold lace on the cuffs of the coat. See Uniform.

Ransom. To redeem from captivity, punishment, or forfeit by paying an equivalent; to buy

out of servitude or penalty; to rescue; to deliver; as, to ransom prisoners from an enemy. *Ransom bill*, a war contract, protected by good faith and the law of nations, by which the captor permits the original owner of captured property to redeem it.

Ransom, George M., Commodore U.S.N. Appointed from Ohio, July 25, 1839.

Promoted to passed midshipman, July 2, 1845; master, June 28, 1853; lieutenant, February 21, 1854; lieutenant-commander, July 16, 1862; commander, January 2, 1863; captain, March 2, 1870; commodore, March 28, 1877.

Served as midshipman in the "Marion," coast of Brazil, 1839–42; and in the "Erie," Pacific Squadron, 1843–44; Naval School, Philadelphia, 1845.

As passed midshipman at the Naval Observatory, Washington, 1845–46; seven months in the war on the coast of Mexico, 1847; Naval Observatory, 1847–48; in the "Portsmouth," coast of Africa, 1848–50; in the "Relief," 1851–52.

As master in the "Michigan," on the lakes, 1853–55.

As lieutenant in the "Perry," "Dolphin," and "Jamestown," coast of Africa, 1855–57; ordnance duty at Boston, 1857–59; in the "Narragansett" and "Saranac," 1860–61, on the Pacific Station.

As lieutenant-commander, commanded the "Kineo," of Farragut's fleet, in the Mississippi River, 1862–63.

As commander, commanded the "Mercedita," on special service in the West Indies, from April to August 24, 1863; the "Grand Gulf," North Atlantic Blockade, 1863–64; the "Muscoota," 1863, having a general supervision, by appointment, of blockading vessels in the East Gulf Squadron; the "Algonquin," from January 18 to March 21, 1866, in a trial with the "Winooski" in Long Island Sound; at League Island, Pa., as executive, 1867–69.

As captain, commanded the ironclad "Terror," North Atlantic Fleet, 1870; at the New York Navy-Yard as executive, 1871–73; commanded the frigate "Colorado," North Atlantic Fleet, 1873–75; and the frigate "Franklin," from December 9, 1876, to March 2, 1877, on special service.

As commodore, commanded the Naval Station at Port Royal, S. C., from June 3, 1878, to January 14, 1879, and since then in command of the navy-yard and station at Boston, Mass.

Rape-oil. A thick yellow oil expressed from rape-seed, used in lamps and light-houses.

Raper. An old term for a rope-maker.

Rap-full. A term applied to the sails of a ship close-hauled, when every cloth draws.

Rapparee. A smuggler, or one who lives on forced hospitality.

Ras Algethi. The star *a Herculis*.

Ras Alhague. The star *a Ophiuchi*, nearly on the line from Antares to Vega, and 12° north of the equinoctial.

Rasee. See RAZEE.

Rasing-iron. An implement used in clearing a seam of pitch and oakum.

Rasp. A species of file on which the cutting prominences are distinct, being raised by punching with a point instead of cutting with a chisel.

Ratcher. An old term for a rock.

Ratchet. A bar, or a revolving cylinder or disk, having angular teeth or notches cut upon its surface or edge, into which a pawl or catch drops, to prevent backward motion of a resistance to be overcome, during a temporary cessation of the moving force; also, an arrangement by which a rectilinear or rotative motion in one direction is, by means of a pawl attached to an oscillating lever or handle, communicated to a sliding bar or rotating disk.

RATCHET DRILL-BRACE. A drill-brace by which a drill is rotated by means of a ratchet, consisting mainly of an oscillating handle or lever provided with a spring pawl acting upon a notched ring or disk fitted to the drill-socket. The drill is "fed" to its work by means of a screw in the end of the socket bearing against an adjustable standard.

RACHET-SABOT. See ORDNANCE.

Rate. The class to which a man-of-war belongs by reason of her tonnage and armament. (See CLASSIFICATION.) In all navies the rates change as improvements are made in ordnance and construction. Thus, in the British navy, at one time, the first-rates comprehended all ships of 110 guns and upwards; they had 42-pounders on the lower deck, the calibre diminishing on the upper decks, to 6-pounders on the quarter-deck and forecastle; they carried from 750 to 900 men. Second-rates mounted 90 to 110 guns. Third-rates, 80 to 90. Fourth-rates, 60 to 80,—comprehended under the general term "frigates" and never appearing in the line of battle. Fifth-rates mounted from 32 to 60 guns. Sixth-rates embraced all vessels carrying fewer than 32 guns. Since the introduction of massive ordnance a first-rate may carry but 1 or 2 guns.

Rate is also the daily variation of a time-piece. *To rate*, to ascertain the rate of a time-piece. (See CHRONOMETER.) Also, to appoint a sailor to a higher grade. See RATING.

RATED SHIP. In former times, a *post-ship*.

RATING, or RATE. The position held by a man before the mast. When a man is rated by the commanding officer, he may be disrated by the same authority; otherwise, it requires the sentence of a court-martial.

Ration. The daily allowance of food to an officer, seaman, or marine. Its component parts are established by law, but may be varied by the Secretary of the Navy, or, when necessary, by the senior officer present in command; the latter may also, in case of necessity, diminish the allowance, but in such case payment must be made to the persons whose allowance is diminished according to the scale of prices established at the time of such diminution. Officers are entitled to one ration, or to commutation therefor, while at sea or attached to a sea-going vessel. The commutation price of the navy ration is fixed by law at 30 cents. Rations are allowed to midshipmen on the active list whether on sea-duty or not. Officers on the retired list are not entitled to rations. See PAY CORPS.

Rational Horizon. See HORIZON.

Ratlines. Small lines traversing the shrouds parallel with the water. They are from 14 to 16 inches apart, and serve the purpose of a ladder. Every fifth ratline extends to the swifter, and is called a *sheer-ratline*.

RATLINE-STUFF. Small stuff having from 12 to 24—generally 18—threads.

Rat's-tail. The tapering end of a rope. Also, the round tapered file used for enlarging holes in metal.

Rattan (Malay, *rotan*). The stem of a cane, of the genus *Calamus*, used for wicker-work, seats of chairs, etc. In the Eastern seas they constitute the chief cables, even to 42 inches circumference, infinitely stronger than hemp, light, and not easily chafed by rocks; very useful also to seamen for brooms, hoops, hanks for sail, etc.

Rattle Down. To hitch and seize the ratlines in their proper places.

Rave-hook. A hook iron implement used in cutting the butts of planking to afford sufficient opening for calking.

Raven's-duck. A fine quality of canvas for sails.

Ray. A flat rhomboidal fish with a rough skin; genus *Raia*.

Raze. To mark timber from a mold with a razing-knife. To cut down.

Razee. A vessel reduced by a deck; as, a line-of-battle ship converted into a frigate. *To razee*, to cut down.

Razor-back. The fin-whale (*Balænoptera*), so called from its prominent dorsal fin. It usually attains the length of 70 feet.

Razor-bill. A sea-fowl allied to the auks, *Alca torda*.

Razor-fish. A small fish of the Mediterranean,—*Coryphœna novacula*,—prized for the table. The *razor-shell*. See SOLEN.

Reach. A straight part between the curves in a stream. *To head-reach*, to forge ahead in stays.

Read, George Campbell, Rear-Admiral U.S.N. Born in Ireland; died at Philadelphia, August 22, 1862. Midshipman, April 2, 1804; lieutenant, April 25, 1810; commander, April 27, 1816; captain, March 3, 1825; rear-admiral, July 31, 1862. After the action between the U. S. frigate "Constitution" and the British frigate "Guerriere," August 19, 1812, in which his gallantry was conspicuous, he was selected to receive the sword of Capt. Dacres. October 25, 1812, he was present in the action between the "United States" and "Macedonian." At the time of his death he was governor of the Philadelphia Naval Asylum. He was a gallant and courteous officer, and of a commanding personal appearance.

Ream. To enlarge a cylindrical cavity; as, to ream out the bore of a gun. To shift the position of a vessel in fishing.

Rear. The farthest aft; as, a rear squadron.

Rear-Admiral. See ADMIRAL.

Rearing. Tumbling home,—applied to a ship's upper works.

Reasty. Rancid or rusty pork or butter, etc.

Réaumur's Thermometer. A thermometer named after its inventor. The freezing-point of water is marked 0°, and the boiling-point 80°.

Reballing. The catching of eels with earthworms attached to a ball of lead suspended by a string from a pole.

Rebate. See RABBET.

Receiver. In the compound steam-engine, a chamber which receives the steam expelled from the high-pressure cylinder and delivers it to the low-pressure cylinder. While the steam is retained in the receiver it is superheated by means of steam-jackets or other apparatus.

Receiving-ship. A ship stationed permanently in a harbor for the purpose of recruiting seamen and holding them in readiness for a cruiser.

Recife, also called Pernambuco, a city of Brazil, on the Atlantic, in lat. 8° 3′ 6″ N., lon. 34° 51′ 7″ W. It is divided into three distinct quarters, viz.: San Pedro, Goncalves, São Sacramento, and Boa Vista. It is the landing-place of a telegraph cable to Lisbon, and is also a railway terminus. The port is defended by 4 forts, and the harbor is protected by a large reef of rocks, and is accessible to vessels drawing not over 12 feet of water. It has a considerable trade with European ports, and the principal exports are cotton, sugar, and dye-wood. Pop. 117,000.

Reckoning. The ship's position as determined by observations and calculations. A vessel is *out of her reckoning* when her true position differs materially from the one in which she was calculated to be. See DEAD-RECKONING.

Recruiting for the Marine Corps. Men to enlist in the marines must be able-bodied, unmarried, and between the ages of 21 and 35 years. They must be not less than 5 feet 6 inches in height, of good character, and not addicted to the use of liquor. They must be able to read and write English properly as well as speak it; and no minors are wanted at all. Marines who have become infirm after 20 years' service, or who have been discharged for wounds received or sickness brought on in the service, are entitled to the benefits of the U. S. Naval Asylum at Philadelphia, Pa. The would-be recruit is required to swear that he is qualified in all respects, and it is impressed upon him that if he swears falsely he commits perjury, a crime punishable with 8 years' solitary confinement and $500 fine. The medical examination is as prescribed by the army and navy regulations. Particular attention is paid to the danger of color-blindness. It is most difficult to obtain the kind of men wanted, and the rejections average 9 to 10. When a man applies to enlist, the recruiting-officer's first care is to see that he has not been entrapped, or induced by false representation to enter the service. He personally explains the exact nature of the service, the length of the time, the pay, clothing, rations, and other allowances to which each soldier is entitled. It is incumbent upon him to be present at the examination of the recruit by the medical officer. Recruits are forwarded, under charge of a non-commissioned officer, from the rendezvous to the marine barracks designated by the colonel commandant.

The examination of privates for advancement to corporals consists of questions in reading, writing, and the simple rules of arithmetic, as to his knowledge of the duties of corporals and of the school of the soldier and company. The examinations for corporals to be sergeants is the same, with the addition that it is required the man shall have a knowledge of keeping the necessary accounts, making out muster-rolls, instruction for skirmishers, and the duties of a sergeant.

The following tables show respectively the strength of the marine corps at different periods of its history; the pay of non-commissioned officers, musicians, and privates; and the allowance of clothing to a marine during each year of his term of enlistment:

	Col. Comdt.	Comd. Staff.	Colonel.	Lieut.-Colonels.	Majors.	Captains.	First Lieuts.	Second Lieuts.	Non.-Com. Staff.	Sergeants.	Corporals.	Musicians.	Drummers.	Fifers.	Privates.
The strength of the marine corps, under the act of July 11, 1798, establishing and organizing a corps of marines, was	...	...	...	...	1	4	16	12	...	48	48	...	16	16	720
Under the act of 1799	...	...	...	...	1	4	18	18	...	56	48	...	25	25	890
Under the act of March 3, 1809	...	...	...	1	1	6	20	18	...	56	233	...	25	25	1484
Under the act of April 16, 1814	...	...	...	1	2	20	32	38	...	117	233	...	46	46	2180
Under the act of March 3, 1817. (Peace establishment.)	...	...	...	1	...	9	24	16	...	73	73	...	21	21	750
Under the act of June 30, 1834	1	...	...	1	4	13	20	20	4	80	80	...	30	30	1000
Under the act of March 3, 1847	1	4	...	1	4	17	24	24	4	105	105	...	55	55	2000
Under the act of July 25, 1861	1	5	1	2	4	20	30	30	4	200	220	30	60	60	2500

The grade of brigadier-general was established March 2, 1867, and abolished 6th June, 1874.

Pay-Table of Non-commissioned Officers, Musicians, and Privates of the U. S. Marine Corps.

Grades.	First Period of 5 Years' Service.	Second Period of 5 Years.	Third Period of 5 Years.	Fourth Period of 5 Years.	Fifth Period of 5 Years.
	Per month.	*Per month.*	*Per month.*	*Per month.*	*Per month.*
Sergeant-major	$23	$27	$28	$29	$30
Quartermaster-sergeant	23	27	28	29	30
Drum-major	22	26	27	28	29
First sergeant	22	26	27	28	29
Sergeant	17	21	22	23	24
Corporal	15	19	20	21	22
Drummers and fifers	13	17	18	19	20
Privates	13	17	18	19	20
Leader of the band	79	81	82	83	84
Musician, first-class	38	40	41	42	43
Musician, second-class	24	26	27	28	29
Musician, third-class	21	23	24	25	26

All enlisted men, except musicians of the band, serving on a first period of 5 years' service, are entitled to $1 per month for the 3d year, $2 per month for the 4th year, and $3 per month for the 5th year's service, in addition to the sums given in the first column above, which additional amounts are retained until expiration of service, and paid only upon final settlement and *honorable* discharge.

One dollar per month is retained from all enlisted men (except the marine band) serving under a re-enlistment. This retained pay is not included in the above table, and is to be credited and paid only upon final settlement and *honorable* discharge from service.

ALLOWANCE OF CLOTHING.

Recapitulation (for regular issues only).

	Clothing.	Full-dress Hats.	Pompons.	Caps. Undress.	Caps. Fatigue.	Caps. Storm.	Caps. Covers.	Caps. Ornaments.	Coats. Full-dress.	Coats. Undress.	Epaulet, bullion (sets).	Fatigue Jackets.	Overcoats.	Field-music. Full-dress Suits.	Field-music. Boys' Jackets. Full-dress.	Field-music. Boys' Jackets. Undress.	Gloves (pairs).	Trousers. Woolen.	Trousers. Linen.	Shirts. Flannel.	Shirts. Linen.	Drawers.	Socks (pairs).	Shoes (pairs).	Arctic Shoes (pairs).	Blankets.
Allowance.	First year	1	1	1	1	1	2	2	1	1	1	1	1	1	1	1	4	2	3	2	3	2	2	3	1	1
	Second year	...	...	...	1	...	2	1	...	...	...	1	...	...	...	...	4	2	1	2	2	2	2	3	...	...

	Total	1	2	3	4	1	10	7	2	3	2	5	1	2	2	3	20	8	8	10	11	10	10	15	1	2

Redd. The spawn of fish. Also, the burrow scooped out by salmon in which to deposit their ova.

Red-eye. A fish of the carp family (*Leuciscus erythrophthalmus*), so named from the color of the iris; called also *rudd*.

Red-hot Shot. Shot made red hot in a furnace and used, before the introduction of shell, for incendiary purposes.

Red Pine (*Pinus rubra*). The red spruce.

Red-short Iron. Iron brittle when heated, and difficult to weld.

Reduce. To degrade to a lower rating.

Reef. That portion of a sail by which it is decreased or increased according to the force of the wind. Square-sails are reefed on the head; fore-and-aft sails are reefed on the foot; a lower studding is sometimes so fitted as to be reefed diagonally. *Close reef*, the last reef that can be put in. *Monkey-reefed*, the situation of sail with the yard on the cap and the reef-tackles hauled out. See BALANCE-REEF.

REEF-BAND. A strip of canvas stitched across the sail to support the strain of the reef-points.

REEF-CRINGLE. A cringle on the leech of a sail, through which the reef-earing reeves. See CRINGLE.

REEF-EARING. A small line used in reefing to haul up and secure the reef-cringle to the yard.

REEFER. A familiar term for a midshipman.

REEF-KNOT. A square knot; a knot used in tying reef-points,—the end parts come out parallel with the standing parts, and the knot does not jam.

REEF-PENDANT. A pendant hooked to a cringle on the leech of a course. In reefing, the clew-jigger is hooked into the thimble in the opposite end. See REEF-TACKLE.

REEF-POINTS. Short lengths of line fitted to the reef-band at equal distances from each other, and used to secure the reef-band to the yard. They are fitted in a variety of ways. Beckets are generally preferred for the first reefs of a topsail.

REEF-TACKLE. A tackle shackled; a cringle on the leech of a sail below the reef-bands; the upper block is secured at the extremity of the yard-arm, the fall leading to the deck. When the tackle is hauled on, the upper part of the leech is slacked so that the men can haul the reef-cringle up to the yard.

REEF-TACKLE CRINGLE. A cringle below the lowest reef-band, to which the reef-tackle is shackled. See CRINGLE.

Reel. A frame turning on its axis, upon which lines, hawsers, hose, etc., are wound.

Reem. To open the seams of a vessel by means of a reeming-iron.

Reeming. A term used by calkers for opening the seams of the plank with reeming-irons, that the oakum may be more readily admitted. This may be a corruption of *rimer*, for opening circular holes in metal.

REEMING-BEETLE. A heavy mallet hooped with iron, and used by calkers in striking a reeming-iron.

REEMING-IRON. A peculiar-shaped iron used by calkers to open the seams of wooden ships previous to calking.

Reeve. To pass, as a rope, through any aperture.

REEVING-LINE BEND. A bend used for uniting ropes or small hawsers; each end is half-hitched over and stopped along the opposite part.

Reflecting Circle. An astronomical instrument, the same in principle as the sextant, but the limb forms a complete circle.

Reflux. The running out of the tide.

Reformades (*Eng.*). The sons of the nobility and gentry who served in the navy under letters from Charles II., and were allowed table-money and other encouragements to raise the character of the service.

Refraction. The change of direction suffered by a ray of light in passing from one medium to another of different density. The incident and refracted rays lie in the same plane with the perpendicular to the surface at the point of incidence and on both sides of it. The sine of the angle of incidence bears to the sine of the angle of refraction a ratio dependent only on the nature of the media, and on the nature of the light.

REFRACTION, ASTRONOMICAL. The change in direction experienced by a ray of light from a heavenly body in passing through the earth's atmosphere. The term *refraction* is also applied to the correction to be applied to an altitude to reduce it to what it would be if the body were viewed through a medium of uniform density; and is, of all astronomical corrections, the most difficult to determine with accuracy. The effect of refraction is to cause the heavenly bodies to appear higher than they actually are. The refracting power of the atmosphere varies with its density, which is affected by its temperature and its moisture. In the zenith there is no refraction; near the zenith it is nearly proportional to the tangent of the apparent zenith distance,—the law, however, becomes complicated as we approach the horizon, where the refraction is greatest. At the horizon the refraction amounts to 33′, which is rather more than the apparent diameter of the sun or moon, so that when the lower limbs of those bodies are in the horizon, the bodies themselves are actually below it. The tables of refraction are constructed on the supposition that the barometer stands at 30 inches, and the temperature is 50° F., the corrections for other heights of thermometer and barometer being given in auxiliary tables.

REFRACTION, TERRESTRIAL. The change in position of a terrestrial object, due to the difference in density of different portions of the atmosphere. It is subject to great irregularity, and the amount varies $\frac{1}{8}$ to $\frac{1}{23}$ of the intercepted arc. The effect on the sea-horizon is of importance to the navigator. See DIP.

Refusal of a Pile. Its stoppage or obstruction, when it cannot be driven farther in.

Regatta. A rowing-match formerly peculiar to the republic of Venice; but the term is now applied to yacht and boat races in general.

Register. The enrollment of a ship at the custom-house, which confers peculiar privileges upon national-built ships. *Registry* is the evidence of such enrollment, and is the security of the ship's title.

Register, or Counter. In the steam-engine, an instrument for recording the number of revolutions made by the shaft. It consists essentially of a case containing a number, usually six, of suitably supported rings or disks, the periphery of each of which is marked with numbers from zero to 9, inclusive. The rings or disks are covered by a plate having openings to expose one figure of each, all the displayed figures appearing in a horizontal row. The first ring is, by mechanism, attached to any convenient part of the running-gear of the engine, moved through the space of one figure, or one-tenth of a revolution, at each revolution of the shaft, counting units; at the completion of each of its revolutions it turns the adjacent ring through the space of one figure counting tens; the second wheel moves the third in the same manner, counting hundreds; and so on to the last ring, when, if six rings are used, the highest number registered will be one less than a million, or, supposing the instrument to start from zero, one million revolutions will have been made when all six rings simultaneously return to zero. The reading of the register, or "counter," is recorded in the steam-log at the end of every hour.

Registers, United States Navy. Prior to 1814 no official annual navy register was issued from the Navy Department. Between 1798 and 1814 several lists of officers in the service were

published, containing the names of the officers in service at the date of their publication. The oldest separate publication of a navy list is a small 12mo of 32 pages, entitled:

"An Original and Correct List of the United States Navy, containing a list of the ships in commission and their respective force; a list of officers and their rank, as well those belonging to the navy as the marine corps; and a digest of the principal laws relating to the navy, etc., etc., etc. By Charles W. Goldsborough. City of Washington, November, 1800. Copyright secured according to law."

This register contains a list of the captures of French armed vessels by the ships of war of the United States during the quasi-war with France, amounting to 72; and it appears by it that the *personnel* of the navy then comprised 26 captains, 9 master-commandants, 109 lieutenants, 7 commanders of galleys, 35 surgeons, 28 surgeon's mates, 22 sailing-masters, 26 pursers, 359 midshipmen, 1 lieutenant-colonel commandant of marines, 4 captains, 18 first lieutenants, 18 second lieutenants of marines, 16 navy agents, and 2 navy constructors. In 1875 fifty copies were reprinted at my request by the chief of the Bureau of Construction in an octavo pamphlet of 12 pages.

The American State Papers, volume on Naval Affairs, contains a list of the officers in 1806, differing somewhat from the register for 1805–6,—published in the Philadelphia "Gentlemen's Annual Pocket Remembrancer" for the year 1806, which was reprinted with my annotations in 1875,—also a list of the officers of the navy and marine corps, February 3, 1812, with a statement of their rate of pay and rations allowed; a list for February 21, 1814, giving the date of appointment or commission of the officers, and a list of the vessels of the navy, with their rates, stations, and by whom commanded on the 4th of March, 1814; also another list for 1814, probably at the close of the year, which, in addition to the names, gives the rate of pay and the employment of each officer. The next list in the volume is the first of the series of navy registers, which has been continued annually ever since in compliance with a resolution of the Senate of the United States, passed December 13, 1815.

The volume also contains annual lists of the officers and their stations from 1818 to 1825, inclusive.

In 1813 there was published in Boston, in a 12mo pamphlet of 105 pages, "A Complete List of the American Navy, showing the name, number of guns, commanders' names, and stations of each vessel, with the names of all the officers in the service for October, 1813, and Steele's list of the navy of Great Britain for July, 1813. Boston. Published by Russell, Cutter & Co., and Joshua Belcher, 1813."

The preface informs us of the design and scope of the publication:

"In preparing the following pages for the press great pains have been taken to present to the public a more correct list of the American navy than has ever been published. Such a list, it is believed, is now completed, and the compiler is much indebted to the politeness of several gentlemen of the navy for the corrections which could not otherwise be obtained.

"The latest Steele's list to be procured is so far republished as to convey all the information respecting the British navy which possesses an interest for the general news reader.

"It is intended to publish every three months a corrected edition of these lists if the sale of the present promises encouragement to the undertaking.

"The deep and general interest which has been excited in the public mind by the valorous achievements of our naval heroes induces a belief that the permanent establishment of a complete list of the American navy must receive adequate patronage. Boston, September 30, 1813."

The anticipations of the publishers do not seem to have been realized, as no further lists appear to have been issued by them, and the Senate resolution of 1815 soon after rendered the printing of a register by private parties unnecessary. In addition to a list of the officers and ships of the United States navy and ships of the royal navy, the book contains an account of all the British vessels of war taken or destroyed in 1812 and 1813 up to the date of its publication; also an obituary of officers who had deceased during the war.

A register for 1815 was published in the "Naval Monument," a history of the naval events of the war of 1812–14, published in Boston in 1816, and another for the same year in the *Analectic Magazine.*

Registers for 1835 and 1836 were printed in the *United States Naval Magazine*, published under the auspices of the Naval Lyceum at the Brooklyn Navy-Yard.

In 1835, Benjamin Homans published a navy register, corrected to July 1, which was to be, but never was, continued annually. In 1843 and 1844, the same person published several quarterly registers, which were discontinued for want of patronage.

In 1848, Messrs. Mechlin & Winder compiled and published a General Register from 1798 to 1847, inclusive, the title of which was:

"A General Register of the Navy and Marine Corps of the United States alphabetically arranged, containing the names of all officers of the navy and marine corps, military and civil, commissioned and warrant, who have entered the service since the establishment of the Navy Department in 1798; showing the dates of their original rank and entry, the dates of their promotions to higher grades, and in what manner and when they left the service, if not still in it. To which is appended the Constitution of the United States, and a revised edition of all the laws in relation to the navy and marine corps, with reference to the 'Statutes at Large,' with an index. Compiled from the official records of the Navy Department, by authority of the Hon. John T. Mason, Secretary of the Navy, by Mechlin & Winder, attorneys and agents, office opposite War and Navy Departments, Washington City. Washington, C. Alexander, printer, 1848."

Many persons are not aware of the data, essential to the biographer and genealogist, which are contained in the United States Navy and Naval Academy registers. I will therefore note what may be found in them. Every Congressional district of the United States is entitled to be

represented by one cadet at the Naval Academy. Whenever a cadet dies, resigns, is dismissed, or graduates from the Academy, the vacancy is immediately filled by the member of the House, or Senator then in office, appointing a successor. The President of the United States also has the appointment of ten cadets at large, who are usually the sons of naval or military officers, or of his personal friends. Thus the Naval Academy has at all times a representative from each Congressional and Senatorial district of the United States, plus 10 appointed "at large" by the President.

No candidate is admitted, however, into the Naval Academy as a cadet midshipman until he has passed a satisfactory examination before the "Academical Board," and is, in the opinion of a medical board comprised of three medical officers of the U. S. navy, found in all respects physically sound, well formed, and of a robust constitution qualified to endure the arduous labors of an officer of the navy. All candidates are required to certify on honor their precise age, and none are examined who are under 14 or over 18, the prescribed limits as to age.

The candidate having passed the preliminary examinations, his height, weight, and lifting power are taken, and recorded in a register kept by the surgeon of the Academy. A like entry is recorded beneath it when he leaves the institution. A comparison of the two records shows his physical development while an under-graduate.

Immediately upon the cadet's admission, his name is enrolled upon the Academy register, with the name of the State from which he is appointed, the date of his admission to the Academy, and his age at admission in years and months, and this is printed in the first Academy register issued after his appointment. This information is continued for each academic year until he graduates, and there is added to it, in succeeding registers, his standing in his class each year, his order of merit in each of his studies and practical exercises, the sum of the demerits he has received during the year, and the total amount of his sea-service in practice-ships. There is also an account opened with each cadet in a large day-book, in which is recorded in full the nature of his offenses against good order and discipline, and the penalty exacted. When a cadet passes a whole month without receiving any demerit, 15 demerits are deducted from the number previously charged against him. If he receives 300 demerits he loses his position in the Academy. After graduation, a general merit-roll of the graduating class is made, to show the sum of the merits of each cadet in his several studies and exercises, together with his standing in the class at graduation, and this is printed in the Academy register.

The annual navy register also contains the names of the cadet midshipmen at the Naval Academy, alphabetically arranged in their classes, with the name of the States of their birth, the States from which appointed, the States of which a resident, and the date of their entering the Academy.

After graduation, the midshipman's name is entered on the navy register in his order of rank; and while the information previously given concerning him as a cadet on the navy register is continued, there is added the date of his graduation, his present duty, station or residence, his total sea-service (in years and months), total shore or other duty, how long employed, how long in the service, and the date of the expiration of his last cruise at sea.

On being promoted to the next higher grade, the date of graduation is omitted, and instead is shown the date of his present commission, and in another column his sea-service under present commission, and these columns are continued through all subsequent promotions. Thus, by an examination of successive registers, the date of each promotion and the amount of sea-service under it can be ascertained.

The same or similar information is given respecting the medical, pay, engineer, and other staff-officers not graduates of the Naval Academy.

The navy register also contains a list of the deaths, resignations, or dismissals during the preceding year, with the date of their occurrence, and in case of death, the place of death; also a list of all the retired and reserved officers, and a table exhibiting the pay of all officers of the navy and marine corps, whether at sea, on shore-duty, on leave, on waiting orders, or retired.

The total amount of the pay and mileage actually received by each and every officer of the navy and marine corps is presented to Congress under a general law, and has been usually, if not always, annually printed in a separate document.

In addition to the annual register, which is brought up to the 1st of January and is usually issued about the 1st of March, since 1866 there has been a register issued in July, giving the name and rank of every officer in the naval service, the State of which he is a resident, the date of his present leave or order, and present duty, station, or residence. With regard to officers on the retired list, it gives the law under which each officer was retired, his name and rank, the State of which he was a resident when appointed, the date of his retirement, his rank when retired, by which his pay on the retired list is regulated, and his present place of residence or address.

Annual official navy registers have been published since 1815, in compliance with a resolution of the U. S. Senate of December 13, 1815; the Naval Academy registers since 1858.—*George H. Preble, Rear-Admiral U.S.N.*

Register-ship. A Spanish plate-ship or galleon.

Regular. The *regular* army or navy, in the United States, is that portion of the land or sea forces which is permanently maintained in the service of the Union, as contradistinguished from that which is called into service temporarily in time of war.

Regulator. A valve, with necessary attachments, for instantaneously controlling the quantity of steam admitted to an engine either by hand or by means of an automatic governor. When operated by hand it is commonly called a *throttle-valve.*

Regulus. The star *a Leonis.* The word is a translation of the Greek name *basiliskos*, little king. In the constellation *Leo* six stars form the rude outline of a sickle, Regulus being at the end of the handle. See Leo.

Reid, Samuel Chester, Sailing-Master U.S.N. Born in Norwich, Conn., August 25, 1783; died

in New York City, January 28, 1861. He went to sea at 11; was captured by a French privateer, and was 6 months a prisoner at Basseterre. He served as acting midshipman in the "Baltimore," in Commodore Truxtun's West India Squadron, and during the war of 1812 commanded the privateer brig "Gen. Armstrong," with which he fought one of the most remarkable naval battles on record, at Fayal, September 26 and 27, 1814. Her force was 7 guns and 90 men. She was attacked by the boats of the "Plantagenet," 74, "Rota," 44, and "Carnation," 18. Reid succeeded in thoroughly disabling and defeating the enemy, and scuttled his own vessel to prevent her capture. The British lost 120 killed and 130 wounded. The Americans had 2 killed and 7 wounded. The attack upon the "Armstrong," in a neutral port, led to a protracted diplomatic correspondence, but the arbitration of Louis Napoleon decided the case against the Americans. Capt. Reid was appointed a sailing-master in the navy, and held the office till his death.

Reigning Winds. The prevailing winds.

Reinforce. An additional thickness given to an object to enable it to withstand strain or pressure brought upon a certain point. The part of a gun having the thickest walls; it extends from the base-line to the chase.

Relief-valve. A valve confined to its seat by adjustable weights or springs, so regulated that it will open under any suddenly accumulated pressure; as, *cylinder relief-valves* or *snifting-valves*, which release water of condensation, or that due to priming of boilers, from a steam-cylinder when obstructing the motion of the piston. Such valves are usually operated by hand.

Relieving-tackles. Tackles hooked to the tiller to steer the ship in case of accident to the wheel or wheel-ropes, and also to assist in steering in heavy weather.

Remark-book. A book containing the navigator's memoranda of hydrographical information.

Remey, William B., Judge-Advocate-General. Born in Iowa. Commissioned as second lieutenant, marine corps, Nov. 25, 1861; frigate "Sabine," S. A. Blockading Squadron, 1861–63; marine barracks, Norfolk, 1863–64.

Commissioned first lieutenant, February 17, 1864; receiving-ship at New York, 1864–65; steamer "Vanderbilt," special service, 1865, and Pacific Squadron, 1866–67; receiving-ship "New Hampshire," Norfolk, 1867–68; marine barracks, Philadelphia, 1868–69; Jan. 13, 1870, reported at headquarters marine corps, as instructor in army code of signals; July 2, 1870, appointed judge-advocate of the marine corps, and served as such until 1873.

Commissioned captain, June 21, 1872; "Colorado," North Atlantic Station, 1873–74; judge-advocate, marine corps, 1874–75; fleet marine officer, South Pacific Station, 1875–76, and of South Atlantic Station, 1876–77; acting adjutant marine corps, October to December, 1877; marine barracks, Norfolk, Dec. 1877, to May, 1878; member Board of Inspection, May to July, 1878; acting judge-advocate-general, Navy Department, July, 1878, to June, 1880.

Commissioned judge-advocate-general of the navy, with the rank of colonel in the marine corps, for the term of 4 years from June 9, 1880.

Render. To pass freely, as a rope through a block.

Rendezvous. The port or place of destination where the several ships of a fleet are appointed to join company.

Rends. Large shakes or splits in timber and plank.

Repeat. To *repeat* a signal, to duplicate a signal intended for a third ship, that it may be more easily read.

Repeater. One of three pennants which indicate, respectively, that the first, second, or third flag in a hoist of signals is duplicated.

Repeating Circle. An astronomical circle which repeats the measurement of an angle without multiplying the single reading of the instrument, thus theoretically reducing the error of imperfect graduation.

Representation. A collateral statement of such facts not inserted in the policy of insurance as may give the underwriters a just estimate of the risk of the adventure.

Reprisal. A mode of redress granted by the sovereign to one or more subjects for some specific injuries; the grant is by commission or letter of marque.

Requisition. An official demand for stores, etc.

Rescue. A rescue effected by the crew when the captors are in lawful possession is unlawful, and is a resistance within the penalty of confiscation.

Reserve, Royal Naval. The naval reserve of Great Britain is divided into three classes, and consists, by the last returns, of a total of 17,067 men. Of these, 11,930 belong to the first class. The rules for enrollment are as follows: The applicant must be of good character and health; must not be above 30 years of age, excepting in the case of the men of the royal navy, who, if they are able seamen, may be received up to the age of 35. For the first class, the applicant must have had at least 5 years' sea-service within the preceding 10 years, and at least one of these years as able seaman. He must show that he has been to sea within 4 months of the time of his application, and must declare his intention of following the sea 5 years longer. If he cannot prove his application, he must satisfy a board of two naval officers of his fitness.

An applicant for the second class must show 3 years' sea-service, and of this time at least 6 months as ordinary seaman. Men in the coasting trade, or those who are making short voyages, are preferred for the second class.

The third class is made up of boys who have been trained in the mercantile training-ship, the sum of £3 being granted by the government to the management of a training-ship for each boy supplied. He must have been 2 years under training in a ship, subject to inspection by the Admiralty and Board of Trade. He must also be under engagement to serve in a ship at sea. He must be 16 years of age, not less than 5 feet 1 inch in height, 30 inches round the chest, robust, and intelligent; must be able to read and write, and must show satisfactory proficiency in the usual drills on board men-of-war, and in elementary seamanship, and must produce a certificate of good character from the captain of his training-ship. They will be, on attaining 19 years of age, provided they have served 6 months at sea, eligible for the second class, and higher if

qualified. These regulations do not apply to boys from reformatory ships, who are not received.

The enrollment is for 5 years, and 4 enrollments must be served in order to get a pension. No pension is allowed to any one who does not pass from the second into the first class; but half the time passed in the second class is allowed to count for pension in case the individual passes into the first class.

The yearly drill is for 28 days. This may be taken, except in the first year, in periods of 7 days each. There are 9 drill-ships stationed at as many ports, and a number of shore batteries, where the men assemble for drill. Nothing is taught here but the usual arm-drills of the service, no seamanship exercises taking place. While assembled for drill, the men are rated and paid as seamen and ordinary seamen of the navy, and have their traveling expenses paid to and fro. They are required to appear in a uniform cap and dark blue clothing.

Any man desiring to make a voyage of longer duration than 6 months must get leave to do so, this leave never extending beyond a year; nor can a man leave the country until he has made his year's drill. Among the men of the reserve are 47 masters of vessels, 518 mates, and 3815 petty officers in the merchant service.

The retainer for men of the first class is £6 annually; for men of the second class, £2 10s.

The reserves can only be called out by royal proclamation. Their period of service, under such proclamation, is for 3 years, unless war is declared, in which case they may be held 2 years longer.

The master of a merchant vessel who belongs to the naval reserve may fly the blue ensign, if he is provided with an admiralty warrant, and if 10 at least of his crew are men of the reserve.

The estimates for the reserves for the year 1880-81 are £213,883, of which amount the annual retainer amounts to £7900; drill-pay and lodging allowance to £37,000; erection and repair of batteries for drill, £7000; sea-pay of officers and crews of the naval reserve drill-ships, £24,552.

Great efforts are made to attract the fisherman class to this force, as these men and those serving in coasting vessels are always at hand, and can attain their yearly drills with less difficulty than can those making long voyages.—*F. E. Chadwick, Lieutenant-Commander U.S.N.*

Respondentia. A bond which is a loan on the pledge of the cargo, generally a personal obligation of the borrower, and not a specific lien on the goods unless stipulated. It amounts at most to an equitable lien on the salvage in case of loss. See BOTTOMRY.

Ret. To soak in water, as in seasoning timber, hemp, etc.

Retard or Age of the Tide. The interval between the transit of the moon and the making of the tide. See TIDE.

Reticule. The system of cross-wires in the focus of an astronomical instrument.

Reticulum. See CONSTELLATION.

Retirement. The legally established process by which an officer worn by long service, superannuated, or disabled by wounds or disease, is honorably withdrawn from active service. The whole number of officers thus withdrawn is termed the *retired list.* Retirement is either voluntary or compulsory. Voluntary retirement takes place in the case of an officer who has been 40 years in the service of the United States, and who makes application to be retired, except he be either a lieutenant-commander, lieutenant, master, ensign, midshipman, passed assistant surgeon, passed assistant paymaster, first assistant engineer, assistant surgeon, assistant paymaster, or second assistant surgeon, in which grades an officer can be retired only on account of physical or mental disability.

Retirement is compulsory in the case of an officer, below the rank of vice-admiral, who has attained the age of 62 years, unless he be of one of the grades last above mentioned, or, being not below the grade of commander, shall have received, during the war for the suppression of the Rebellion, the thanks of Congress for distinguished service; in which latter case he cannot be retired, except on his own application or for disability, until he shall have been 55 years in the service. The other cases in which retirement is compulsory are where an officer having been examined for promotion shall not have been recommended therefor; and where an officer is found by a retiring board to be incapacitated for active service, said incapacity being the result of an incident of the service. If, however, the board find that the incapacity be not the result of any incident of the service, the officer is retired on furlough pay, or *wholly retired,* as the President shall determine. Officers wholly retired receive one year's pay and are dropped.

Retired officers are borne upon the Navy Register in their respective grades, are entitled to wear the uniform, and are subject to the rules and articles for the government of the navy, and to trial by general court-martial. They are withdrawn from command, and cannot be employed on any active duty except in time of war, when the President, by and with the advice and consent of the Senate, may detail them for the command of squadrons and single ships, when he believes that the good of the service requires that they shall be so placed in command. In making such details the President may select any officer not below the grade of commander and assign him to the command of a squadron, with the rank and title of "flag-officer," and the officer so assigned shall have the same authority and receive the same obedience from the commanders of ships in his squadron holding commissions of an older date than his that he would be entitled to receive if his commission were the oldest. Retired officers so detailed may be restored to the active list, if upon the recommendation of the President they shall receive a vote of thanks of Congress for distinguished service, but not otherwise.

Officers on the retired list are entitled to promotion as their several dates on the active list are promoted. In the case of rear-admirals, however, the number of that grade by promotion on the retired list is limited to nine (except that the Secretary of the Navy may promote to the grade of rear-admiral on that list, in addition to the number mentioned, commodores who have commanded squadrons by order of the Secretary of the Navy, or have performed other highly meritorious service, or who, being at the outbreak of the war of the Rebellion citizens of any State

which engaged in such Rebellion, adhered to the flag of the United States), and there can be no promotion to rear-admiral on the retired list while there shall be in that grade the full number allowed by law. Officers promoted on the retired list receive no increase of pay in consequence of such promotion. See EXAMINATION OF OFFICERS FOR PROMOTION AND RETIREMENT, BOARD OF.

Retractor. A device for withdrawing the cartridge-case from breech-loading arms.

Retractus Aquæ. An old law-term for the ebb or return of tide.

Retreat. A call of the bugle or beat of a drum to announce the termination of a drill.

Retrograde Motion. The general motion of all the planets among the stars is eastward or *direct*. When they come into the quarter of the sky which is opposite the sun, their motion is westward, or *retrograde*.

Returns. Reports and statements made periodically.

Return-salute. See SALUTES.

Revenue Marine Service. The first step in this country toward an organized force for the protection of the revenues from duties on imports was made under an Act of Congress, approved August 4, 1790, which provided for building and equipping 10 revenue-cutters, each to be officered and manned by one master and not more than three mates, who should be appointed by the President, and be deemed officers of the customs.

The objects for which the revenue-cutters were thus authorized were specifically set forth in a communication to Congress from Alexander Hamilton, Secretary of the Treasury, and were understood to be mainly for the enforcement of the customs laws throughout the whole extent of the sea-board. Two of the cutters were intended for the coasts, bays, and harbors of New Hampshire and Massachusetts; one for Long Island Sound; one for the bay of New York; one for Delaware Bay; two for the Chesapeake; and one each for the coasts and harbors of North Carolina, South Carolina, and Georgia. Hamilton said, "Boats of from 36 to 40 feet keel will answer this purpose, each having 1 captain, 1 lieutenant, and 6 mariners, and armed with swivels;" and after estimating the first cost of one of these vessels completely equipped at $1000, he continued: "The utility of an establishment of this kind must depend on the exertion, vigilance, and fidelity of those to whom the charge of the boats shall be confided. If they are not respectable characters they will rather serve to screen than to detect fraud. To procure such a liberal compensation should be given. He suggested giving the officers military or naval rank, "which," he added, "will not only induce fit men to engage, but attach them to their duties by a nicer sense of honor." Immediately after the passage of the act, letters were addressed to the collectors of customs at Boston, New York, Philadelphia, and Baltimore, authorizing the construction and equipment of such cutters as were considered suitable for the service in their respective districts. The records of the Treasury Department contain considerable correspondence on the subject of the proposed establishment, and perhaps many obstacles occasioned delay, for the first list of cutters found is dated February 19, 1793, and shows that on October 1, 1792, but 8 of these vessels were in commission, as follows:

Cutter.	Coast on which stationed.	Master.	Rig.	Guns.
Scammel.........	N. Hampshire	Hopeley Yeaton....	Schr.	14
Massachusetts..	Massachusetts	J. Foster Williams	Brig.	"
Argus.............	Connecticut...	Jonathan Maltbie.	Schr.	"
Vigilant	New York.....	Patrick Dennis.....	"	"
Gen. Greene....	Pennsylvania	Jas. Montgomery..	Sloop	10
Active............	Maryland......	David Porter........	Schr.	14
Virginia	Virginia........	Richard Taylor....	"	12
Diligence........	N. Carolina....	Wm. Cook...........	"	....

Two others are mentioned as being in course of construction for the coasts of South Carolina and Georgia. They were probably the "South Carolina" and the "Pickering," subsequently mentioned with others in the above list as co-operating with the navy.

On March 2, 1793, an act was passed authorizing an increase in the number of mariners, and a slight increase of pay for officers and men, the pay having been fixed by the original act, for captain, at $30 per month, and mates, or lieutenants, at $20, $16, and $14, respectively, besides which each officer was entitled to the allowances of an officer of the army of corresponding grade, while the men received each $8 per month and subsistence. This pay was further increased by act of May 6, 1796, which also gave to revenue-cutter officers half of the amounts of fines, penalties, and forfeitures collected upon information furnished by them.

June 14, 1797, an act was approved which authorized the President, if circumstances should thereafter arise which, in his opinion, might render it expedient, to increase the strength of the several revenue-cutters, so that the number of men employed should not exceed 30 marines and seamen to each cutter, "and cause said revenue-cutters to be employed to defend the sea-coast, and to repel any hostility to their vessels and commerce within their jurisdiction, having due regard to the duty of said cutters in the protection of the revenue." It was also provided that the act should continue in force for the term of 1 year, "and from thence to the end of the next session of Congress, and no longer."

The increase of men and addition to the powers and duties of the cutters by this act were doubtless in view of threatened hostilities with France.

In October of 1798, the President, "with a view of producing a concert of action of the naval forces of the United States," placed the armed revenue-cutters at the disposition of the Secretary of the Navy. The revenue vessels selected for this purpose were the "Pickering," "Eagle," "Scammel," "Governor Jay," "Virginia," "Diligence," "South Carolina," and "Gen. Greene." They were employed in cruising among the West Indies, or between the islands and the United States, under command of officers of the navy who had but recently been appointed from the merchant service, and in a few instances from the revenue-cutters. About the close of the year 1798, 4 of these vessels were permanently attached to the navy, and the

others returned to the Treasury Department or revenue service.

On March 2, 1799, an act of Congress was approved which was entitled "An act to regulate collection of duties on imports and tonnage." It embraced many of the provisions of previous acts, with numerous new features which the growth of the nation and experience demanded. Six sections of this act relate to revenue-cutters, and are briefly as follows: The President was empowered, "for the better securing the collection of duties imposed on goods, wares, and merchandise imported into the United States, and on the tonnage of ships or vessels, to cause to be built and equipped so many revenue-cutters, not exceeding 10, as may be necessary to be employed for the protection of the revenue, the expense whereof to be paid out of the product of said duties." For each of said cutters there was to be 1 captain, and not more than 3 lieutenants,—first, second, and third,—and not more than 70 men, including non-commissioned officers, gunners, and mariners. The cutters were to co-operate with the navy whenever the President should so direct. The officers were to be appointed by the President, and be deemed officers of the customs, and, as such, subject to the direction of such collectors of customs, or other officers thereof, as from time to time might be designated for the purpose; and they were empowered, authorized, required, and directed to go on board all ships or vessels arriving within the United States, or within 4 leagues of the coast thereof, if bound for the United States, and to search and examine the same, and every part thereof; and to demand, receive, and certify the manifests required by law, and to affix and put proper fastenings on the hold, hatches, and other communications with the hold of any ship or vessel, and to remain on board the said ships or vessels until they arrive at the port or place of their destination.

The commanders of revenue-cutters were also required to make weekly returns to the collectors of the transactions of their commands, with minute details of all vessels boarded and examined, and all services performed. Such other duties as the Secretary of the Treasury might from time to time enjoin or direct for the collection or security of the revenue were also to be executed by these vessels. New cutters were provided for in lieu of those unfit for service, which were to be sold. A distinctive ensign and pennant for the cutters was also provided for, to be prescribed by the President; and in case any vessel liable to examination or seizure failed to bring to, on being required, or chased by a cutter displaying the ensign and pennant, it was made lawful for the commanding officer to fire at, or into, such vessel after having fired a gun as a signal, and he, or his subordinate, to be indemnified from any penalties or action for damages for so doing; and if any person should be killed or wounded by such firing, and if the commanding officer, or other person acting under his direction, should be prosecuted or arrested therefor, he was to be forthwith admitted to bail. A penalty of $100 was prescribed against the master of any vessel, not in the service of the revenue, who should carry or hoist the ensign prescribed for the cutters.

Another act of same date prescribed the compensation for the commissioned officers, and the rate of wages and rations for non-commissioned officers, gunners, and mariners. The terms of this act, so far as they apply to the powers and duties of officers, have not been changed by subsequent legislation.

The number of cutters employed from 1793 up to 1820 cannot be accurately stated, as the necessary information is not at present accessible. During that period there were frequent disturbances in the foreign relations of the country, which, on account of the limited number of naval vessels, often compelled the government to divert the cutters from their regular duties in anticipation of hostilities, or to engage in actual war.

The causes that led to the reduction of the navy in 1801, to wit: the cessation of hostilities with France, and the necessity for retrenchment in the expenses of the government, operated in like manner to reduce the number of revenue-cutters. The size of the vessels, also, which in some instances had reached nearly 200 tons, was now limited to 130 tons. In 1809, however, the number of cutters was increased, probably on account of the famous embargo act of 1807, which was repealed in 1809, except so far as related to Great Britain and France and their dependencies.

In the war of 1812 the cutters were usefully employed as dispatch-vessels, and for coast defense, duties for which their light draft and good sailing qualities well fitted them, and on several occasions they encountered the enemy's vessels and boat expeditions with creditable results.

The scope of this article does not admit of the details of particular incidents, or the achievements of individuals, but there was one affair in which a cutter was captured after a gallant defense that deserves mention on account of the unusual compliment paid to her commander by his captor. On the night of June 12, 1813, the revenue-cutter "Surveyor," Capt. S. Travis, on the Chesapeake station, was captured by the barges of the British frigate "Narcissus." The enemy was discovered by the cutter when about 150 yards distant; as the latter's guns could not be brought to bear, each of her crew was furnished with two muskets, and their fire was held until the British were within pistol-shot. The engagement was sharp, but the enemy carried the vessel by boarding, losing 3 men killed and a number wounded. Capt. Travis and his crew, 15 in number, were taken on board the "Junon," and the next day the senior officer of the "Narcissus" returned the captain his sword with the following letter:

"HIS MAJESTY'S SHIP 'NARCISSUS,'
"June 13, 1813."

"SIR,—Your gallant and desperate attempt to defend your vessel against more than double your number, on the night of the 12th inst., excited such admiration on the part of your opponents as I have seldom witnessed, and induced me to return you the sword you had so nobly used, in testimony of mine. Our poor fellows have severely suffered, occasioned chiefly, if not solely, by the precautions you had taken to prevent surprise; in short, I am at a loss which to admire most, the previous engagement on board

the 'Surveyor,' or the determined manner by which her deck was disputed, inch by inch.

"I am sir, with much respect,

"JOHN CRERIE.

"Capt. S. TRAVIS, U. S. cutter 'Surveyor.'"

In addition to the active services of the cutters in connection with the war, they found busy employment in the suppression of smuggling and piracy, which had become quite common pursuits of the many adventurers attracted to American waters by the unsettled condition of the country.

From 1820 to 1830 no greater number than 10 cutters were employed in any one year, and the lists of officers during that period contain the names of a few who also belonged to the navy. It appears that in 1821 several officers of the navy, mostly midshipmen, obtained furloughs for one year, with permission to accept temporary appointments in the revenue-cutter service, and this practice continued until the spring of 1832, when it ceased under the terms of a circular issued by Louis McLane, Secretary of the Treasury, dated January 17, 1832, in which it was stated that experience having shown that the employment of officers of the navy in revenue vessels was liable to objection, it was deemed proper to discontinue the practice and keep the two services distinct and separate. Officers of the navy then employed in the revenue-cutter service were informed that their commissions as revenue-cutter officers would be revoked on the 30th of April following, and for the greater efficiency of the cutter service, it was determined that promotions would thereafter be made from among the officers of that service, having due regard to fitness as well as seniority. The most of the navy officers then attached to the cutters returned to their own service, while others, about a dozen, resigned from the navy and retained their commissions in the revenue-cutter service.

At this period there was a gradual extension of the service, and in 1833, 21 cutters are found in commission, fully officered. They were generally schooners, many carrying fore-topsails, and guarded the Atlantic, Gulf, and Lake coasts. During the nullification times of 1832–33, several of the cutters were stationed at and off Charleston, S. C., to enforce the customs laws. Four at least were there in the latter part of 1832, and, joined by two or three others during the winter, remained until the spring, when the troubles ended and the revenue vessels returned to their respective stations along the coast. About this time too (1833), certain of the vessels were engaged in cruising on the coast, under special orders, during the winter months to aid and assist distressed vessels, a duty with which they were familiar, incidentally with former cruises in their regular line of service. This duty afterwards became imperative and annually recurring, under the act of December 22, 1837, by which the President is authorized to cause any suitable number of public vessels adapted to the purpose to cruise upon the coast in the severe portion of the season, "and to afford such aid to distressed navigators as their circumstances may require." After the passage of the act, a frigate, a sloop-of-war, and 3 brigs of the navy were ordered on that service with 8 of the cutters. The naval vessels proved to be too large and unwieldy for the coast service, and were withdrawn at an early day. From this time the protection of commerce in this regard devolved upon the revenue vessels, which have been employed under the act during every winter up to the present time, with such satisfactory results as to earn for the service generally a deserved popularity, especially with all persons connected with the maritime interests of the country.

Early in 1836, several cutters were ordered to Florida to co-operate with the army and navy against the Seminoles, and at one period during that war there were 6 cutters employed, carrying dispatches, transporting troops and supplies, and in cruising along the coast and among the keys, affording protection to the settlers from hostile Indians.

Among other duties performed by the cutters from their first establishment, was the inspection and supply of light-houses and buoys under the direction of collectors of customs. In 1845 the light-houses were placed in charge of the Revenue Marine Bureau, and the cutters were more actively employed than formerly on light-house duty. This continued until the establishment of the present Light-House Board in 1852, when the improved character of that service required vessels especially adapted for its work.

Steamers were first introduced into the revenue-cutter service in 1845, when 4 were put in commission, and 4 others in course of construction. These steamers were built of iron, and being almost the first vessels constructed of that material in this country, were comparatively experimental, and afterwards proved to be unsuitable for the service. In the following year, however, two of them, the "McLane" and the "Legare," with the sailing-cutters "Ewing," "Forward," and "Woodbury," performed efficient service in co-operation with the army and navy on the coast of Mexico. The "McLane" and the "Forward" participated in the naval attack on Tabasco in October, 1846, and subsequently in the attack on Alvarado. They were also engaged in blockading the Mexican Gulf ports, and in conveying dispatches, and for their services generally their officers were highly commended by the commanders-in-chief of the U.S. military and naval forces engaged in the war with Mexico.

After the close of the war these steamers were laid up. A few were afterwards transferred to the coast survey, and the rest otherwise disposed of, so that in 1849 the name of but one was retained on the list of cutters. This was the "Polk," from which the machinery was removed and the vessel rigged as a bark for the Pacific coast, where the new brig "Laurence" had already been sent. In that year there were but 11 cutters in active service, an ill-advised economy having reduced their number instead of otherwise retrenching the expenses caused by the introduction of costly and unsuitable steamers, and correcting the evils that always spring up during a period of war. In a short time, however, the bad results of this reduction being shown in the growth of smuggling and other violations of law, an increase of the service was found necessary, and in 1852, 6 new vessels were authorized. In 1855, 4 new cutters were added by an act which also provided that no person shall be appointed captain, first, second, or third lieutenant who

does not adduce competent proof of proficiency and skill in seamanship and navigation.

In the following year 6 cutters were provided for the lakes, and the next year a side-wheel steamer was authorized. This steamer was afterwards known as the "Harriet Lane," and had a somewhat notable career. She was ordered by the President to co-operate in the naval expedition to Paraguay, and rendered valuable services. In the beginning of the Rebellion she was under fire at the attack upon Fort Hatteras, and during a reconnoissance of the rebel batteries near Norfolk, and was subsequently transferred to the navy.

During the Rebellion the service was considerably increased. Several vacancies occurred by the resignation of officers of Southern birth. To fill these, and supply the additional vessels with officers, many appointments were made from the merchant service, which was also largely drawn upon for the volunteer navy, and several came into the revenue marine who had previously had but little sea experience. Examining boards to determine the professional qualifications of the candidates were then held, as now, but the urgency of the demand for officers compelled the exercise of leniency in the examinations. The cutters were variously employed during the war, some as dispatch-vessels, others in convoying transports or cruising after privateers. The steamer "Naugatuck" took part in the naval attack on Fort Darling, and the revenue-steamer "Reliance," while pursuing blockade-runners on the Maryland shores, was fired into by some land forces of the enemy, and her commanding officer, Capt. Thomas Dungan, was killed.

The same injurious effects which had resulted from the participation of the revenue vessels in former wars were apparent throughout the service with the return of peace.

In 1871, a much-needed reorganization was effected under the then Secretary of the Treasury, Hon. George S. Boutwell. All officers were subjected to a rigid examination as to their professional qualifications, and those found incompetent were removed. The vacancies thus caused were filled by others who had successfully passed competitive examinations. The old and unsuitable vessels were sold, or altered and repaired, and new vessels specially designed for the service were built. The imperfect system under which the service had been managed gave place to a carefully-devised plan, which exacted a strict accountability from all officers in charge of public property, and instituted many wholesome reforms in the expenditure of the appropriations for the service. The establishment of regular boards of examination and the introduction of the competitive system in the promotions to higher grades stimulated the officers generally to industrious application in the studies necessary for their improvement. The result of this reorganization was soon manifested in the increased efficiency of the whole service and the reduction in its annual expenses.

In 1876, an act of Congress was passed which provides as follows: "That hereafter, upon the occurring of a vacancy in the grade of third lieutenant in the Revenue Marine Service, the Secretary of the Treasury may appoint a cadet not less than 18 nor more than 25 years of age, with rank next below that of third lieutenant, whose pay shall be three-fourths that of a third lieutenant, and who shall not be appointed to a higher grade until he shall have served a satisfactory probationary term of two years and passed the examination required by the regulations of said service." Under this act boards of examination are held for candidates for admission to the grade of cadet. The scope of the examination, while searching in its character, covers only the ordinary English branches, but the competitive system being adhered to, the appointments are not controlled by political or personal favoritism.

The cadets are first sent on a practice-cruise at sea in a revenue-cutter detailed for the purpose, and are carefully trained in practical navigation and seamanship. During the winter they are instructed in mathematics and such other studies as will best fit them for the proper performance of their duties as officers. A second cruise at sea is followed by another winter of study and training on shipboard, when, after examination, they are, if found competent, appointed third lieutenants in the service.

By an act of Congress, the Secretary of the Treasury has power to designate other necessary duties for the cutters than those previously mentioned under the act of March 2, 1799. These have come to be various, the cutters having been sent on many special cruises in search of missing vessels, or in the enforcement of the neutrality laws by preventing armed expeditions against neighboring and friendly governments. The suppression of mutiny on board vessels arriving at or sailing from our ports is a frequent service performed by the cutters. Since the acquisition of Alaska, its shores and the neighboring islands have been visited annually by one or more of the revenue vessels on the Pacific coast; and since the withdrawal of the U. S. troops from the Territory, the cutters have afforded the principal means for enforcing the law and protecting the people in that remote country. At this writing (June, 1880) the revenue-steamer "Corwin" is on her way to the Aleutian Islands, with instructions to extend her cruise into the Arctic Ocean, in search of two missing whalers; also to bring back tidings, if possible, of the Arctic exploring steamer "Jeannette."

Under an act passed June 18, 1878, officers of the revenue marine are detailed as inspectors and assistant inspectors of life-saving stations, and act as such under the direction of the general superintendent of that service. For this duty they are well fitted by their familiarity with the coast, as well as from the long association of the two services, which dates back to the first establishment of the life-saving stations, in 1848. While thus employed, however, the officers do not neglect their regular duties in the protection of the revenues, and, with two or three exceptions, remain in command, or are attached to revenue vessels.

A fair estimate of the usefulness of the revenue cutters may be drawn from the following statement, which embraces a period of nine fiscal years, or from June 30, 1871, to June 30, 1879, viz.:

Number of vessels boarded and examined	218,479
" " seized or reported for violation of law	14,192
" " in distress assisted	1,578
" miles sailed and steamed	1,600,679
" lives saved	555

These figures are obtained from the reports of the vessels, made on a form in use only since 1871. If it were practicable to examine all the log-books or reports of the cutters since the first establishment of the service, quite as satisfactory figures would no doubt be shown.

The records of the Treasury Department do not furnish a complete statement of the total value of the services rendered by the cutters to the commerce of the country, but from the reports made during the last 3 years, it is certain that property consisting of vessels and cargoes, imperiled by the sea, of the value of $9,148,435.80, has been assisted and saved by the revenue-cutters, or about five times the total cost to the United States of the whole fleet of revenue-cutters, and it will be apparent that the aggregate would be enormous could it be ascertained for the period since the organization of the service.

There are at present employed in the revenue marine 23 propellers, 8 side-wheel steamers, 1 bark, 1 schooner, and 4 sloops. These vessels are stationed in the principal ports on the Atlantic and Pacific coasts, and in four of the Great Lakes, and their cruising-grounds cover the whole coast of the United States.

Their armament is from 1 to 4 light guns, and sufficient small-arms, according to the size of the vessel and the probable necessities of the station to which they are assigned.

The officers consist of 34 captains, 34 first lieutenants, 34 second lieutenants, 34 third lieutenants and cadets, 23 chief engineers, 18 first assistant engineers, and 27 second assistant engineers.

By act of February 4, 1863, captains in the revenue marine rank with and next after lieutenants commanding in the navy.

First lieutenants with and next after lieutenants.

Second lieutenants with and next after masters.

Third lieutenants with and next after ensigns.

The present duty pay of officers under act of February 28, 1867, is as follows:

Captains	$2500	per annum and	1	navy ration.
First lieutenants	1800	"	"	"
Second "	1500	"	"	"
Third "	1200	"	"	"
Chief engineer	1800	"	"	"
First asst. engineer	1500	"	"	"
Second " "	1200	"	"	"
Cadet	900	"	"	"

The wages of petty officers and crews are regulated by the Secretary of the Treasury from time to time, in accordance with the port wages for merchant seamen in the place where the cutter may be stationed. The number of petty officers and seamen for each vessel is also regulated in like manner according to the size of the cutter and the necessities of her station, rarely exceeding 30, all told, for a first-class vessel.

The whole service is under the direction of the Secretary of the Treasury, and its affairs are conducted by a division of his office, in charge of a chief termed Chief of Revenue Marine, whose responsible duties demand from him good executive ability, legal and scholarly attainments, and good business capacity, while he can avail himself of professional advice from any one of the several competent officers of the service in regard to all nautical matters appertaining to the vessels or the *personnel* of the service.

The general discipline throughout the service is similar to that of the navy.

The revenue marine holds a well-earned and deserved popularity, and is generally recognized as a branch of the public service which increases the receipts of the Treasury, and saves to the commerce of the country each year many times more than the annual expenses for its maintenance.—*J. H. Merryman, Captain U.S.R.M.*

Revenue-cutter. Originally, a sharp-built, single-masted, fast-sailing vessel, armed for the purpose of preventing smuggling, and enforcing the custom-house regulations. The name is now applied to the small steamers of the revenue service.

Reverse-valve. A small conical-faced valve attached to a steam-boiler and so arranged as to open inward and admit air when the atmospheric pressure exceeds that of the steam or vapor within, thus preventing external pressure for which the boiler is not braced. A partial vacuum in a boiler may occur when steam of atmospheric pressure is no longer formed by the fires, and when, with dead or hauled fires, it is permitted to condense while the safety-valve and other atmospheric communications are closed.

Reversing-gear. The mechanism attached to the valve-gear of a steam-engine by which the motion of the engine is reversed. In heavy machinery it is actuated by a steam-cylinder controlled by a screw or hydraulic apparatus.

Reversing-lever. A lever or bar by which the motion of a machine is reversed in direction; as, the reversing lever of a locomotive-engine, which throws either the go-ahead or backing eccentrics of the valve-gear into action, causing the engine to move forward or backward.

Revolution. The time occupied by a planet in passing once around the sun is the time of its *sidereal* revolution; as it cannot be observed from the earth on account of the earth's motion, its length can only be computed. A *synodic* revolution is completed when the planet, the earth, and the sun come again into the same relative positions, as, into conjunction, or opposition.

Reynolds, William, Rear-Admiral U.S.N. Appointed acting midshipman, from Lancaster, Pa., November 17, 1831; first cruise, schooner "Boxer," sloop-of-war "Peacock," coast of Africa, Brazil, East Indies, 1831–34; frigate "Potomac," "Delaware," 74, Mediterranean, 1834–36; Naval School, Norfolk, 1836–37.

Promoted to passed midshipman, June, 1837; "Pennsylvania," 120, Philadelphia to Norfolk, 1837–38; Depot of Charts, Washington, 1838; Exploring Expedition, 1838–42.

Commissioned as lieutenant, September, 1841; frigate "Cumberland," Mediterranean, 1843–44; corvette "Plymouth," Mediterranean, 1845; steamer "Alleghany," "Pittsburgh," Mississippi River, Gulf of Mexico, Brazil, Mediterranean, 1846–49; Bureau of Construction, 1850; invalided, 1850; command of store-ship "Fredonia," Valparaiso, 1855; retired, 1855; naval storekeeper, Honolulu, 1857–61; under surgical treatment, 1861–62.

Commissioned as commander, reserved list, 1862; command of "Vermont," Port Royal, November, 1862; of "New Hampshire," and naval depot, Port Royal, 1863–65; restored to active list, February, 1866; command of "Lackawanna," North Pacific, 1866–69.

Commissioned as captain, July, 1866.

Commissioned as commodore, June, 1870; Chief of Bureau of Equipment, July, 1870–75.

Commissioned as rear-admiral, December, 1873; command of Asiatic Station, flag-ship "Tennessee," April, 1875–77; invalided, August, 1877; retired, December, 1877; died, November 5, 1879.

Rhe. A very old word signifying an overflow of water.

Rhind, Alexander Colden, Commodore U.S.N. Born in New York. Appointed from Alabama, September 3, 1838; attached to line-of-battle ship "Ohio" and sloop "Cyane," Mediterranean, 1839–41; sloop "Warren," West Indies, 1842–43; frigate "Macedonian," coast of Africa, 1843–44; Naval School, Philadelphia, 1844–45.

Promoted to passed midshipman, July 2, 1845; brig "Washington," coast survey, 1845–46; Home Squadron, coast of Mexico, until end of the war; present at Alvarado and Tabasco; steamer "Water-Witch," Home Squadron, 1848; coast survey, schooner "Ewing," to California, 1849–50; sloop "St. Mary's," East Indies, 1850–51; coast survey, 1851–54.

Promoted to master, April 30, 1853.

Commissioned as lieutenant, February 17, 1854; sloop "John Adams," Pacific Squadron, 1855; sloop "Constellation," coast of Africa, 1859–61; commanding steam-gunboat "Crusader," South Atlantic Blockading Squadron, 1862; participated in various small affairs at North Edisto; shore fight at Seabrook's plantation, S. C., the crew of the "Crusader" defeating a rebel mounted force; capture and destruction of rebel works commanding South Edisto, Dawho and Pon-Pon Rivers, for which he received the thanks of the Department.

Commissioned as lieutenant-commander, July 16, 1862; commanding steamer "Seneca," South Atlantic Blockading Squadron, 1862; commanding ironclad steamer "Keokuk," South Atlantic Blockading Squadron, 1862–63; commanding her in the attack on defenses of Charleston, April 17, 1863. In this engagement the "Keokuk" was struck 90 times in 30 minutes; 19 shots pierced her through, at and just below the water-line. Finding it impossible to keep his vessel afloat under such an extraordinary fire, Commander Rhind withdrew from action. Being in smooth water he managed to keep her afloat during the night, although the water was pouring into her in many places; but at 7.30 A.M. on the following morning she went down; the officers and crew were saved, but lost all their effects.

Commissioned as commander, January 2, 1863; commanded steamer "Paul Jones," South Atlantic Blockading Squadron, 1863, and took part in various engagements with Fort Wagner and other defenses of Charleston; commanded steam-frigate "Wabash," flag-ship South Atlantic Blockading Squadron, 1863; commanding steam-gunboat "Agawam," North Atlantic Blockading Squadron, 1864–65, and on duty in James River from May to October, 1864. Engagement with rebel batteries at Deep Bottom, August 13, 1864. Rear-Admiral Lee, in his report of this affair, thus speaks of Commander Rhind: "I take great pleasure in calling the attention of the Department to the gallantry and endurance displayed by Commander Rhind of the 'Agawam,' and the officers and men under his command, in the engagement with three rebel batteries, August 13, 1864, reported to the Department by Capt. Smith, divisional commander on the James River." Commander Rhind received thanks of the Department in letter dated September 7, 1864. In December, 1864, Commander Rhind was detailed by Admiral Porter to command the powder-boat "Louisiana," and on the night of the 23d that vessel was exploded within 250 yards of Fort Fisher, the officers and men being taken off by the steamer "Wilderness." Rear-Admiral Porter, in his official report to the Navy Department, says, "In conclusion, allow me to draw your attention to Commander Rhind and Lieut. Preston. They engaged in the most perilous adventure that was, perhaps, ever undertaken. As an incentive to others I beg leave to recommend them for promotion." Commanding receiving-ship "Vermont," New York, 1866–67; commanding naval rendezvous, New York, 1868; navy-yard, New York, 1869–70.

Commissioned as captain, 1870; commanding "Congress" (second-rate), European Station, 1872–73; light-house inspector, 1876–78.

Commissioned as commodore, September 30, 1876; special duty, 1879; president Board of Inspection, 1880.

Rhodes is the capital of the island of Rhodes, in Asiatic Turkey, and is situated at the northeast extremity of the island, in lat. 36° 26′ 9″ N., lon. 28° 13′ E. It is inclosed by walls, and on the land side is strengthened by ravelins and a moat. On the northeast side two piers projecting form a harbor, and on the north side is another port. Outside of the walls, on the north, are the pasha's palace and the dock-yard. It exports red leather and shoes, which form its principal manufacturing industry. Pop. 20,000.

Rhodian Laws. A maritime code, asserted, but without sufficient proof, to be the basis of the Roman sea-laws. The code published by Leunclavius and others, as a body of Rhodian laws, is a mere forgery of modern times.

Rhodings. The brass cleats on which the axles of the pumps work.

Rhumb. The intersection of a vertical circle with the horizon; a rhumb-line.

RHUMB-LINE. A line which cuts the meridians at a constant angle; the loxodromic curve; the equiangular spiral.

RHUMB SAILING. In rhumb sailing, the ship sails on the rhumb-line joining the place of departure and place of destination. It is the ordinary mode adopted when out of sight of land, as the compass points it out, and on Mercator's chart it appears as a straight line.

Rhydal. A ford or channel joining lakes or broad waters.

Rib. A figurative term for one of the frames of a ship, arising from the comparison of a ship stripped of her planking to the human skeleton. A projection formed upon a metal casting for the purpose of securing strength. *Ribs and trucks*, fragments.

Ribadoquin. A powerful cross-bow for throwing long darts. Also, an old piece of ordnance throwing a ball of one or two pounds.

Ribband. A long piece of oak or pine from 4 to 6 inches square, used to keep the frames in position, after they have been regulated.

RIBBAND-LINE. The same as a diagonal line

in the body plan, the difference in their application being that the ribband-line is taken off by the use of horizontal lines square from the centre-line at the intersection of the frame-line with the diagonal line; while the diagonal line is taken off in a diagonal direction, before the line is applied to the half-breadth to obtain its shape. The diagonal lines cannot be used to prove the cant-lines or frames, while the ribband-lines can be so used.

RIBBAND-SHORE. A shore placed against the ribband upon the frames in order to keep the body in shape.

Ribbing-nail. A nail with a large round head to be driven through a ring.

Ribbon-fish (*Tænioidæ*, from *tænia*, a tape-worm). A family of acanthopterous fishes, so called on account of their compressed and elongated form. They are of very delicate structure, in consequence of which it is difficult to obtain perfect specimens. They have a silvery skin, a long dorsal fin often uniting with the tail-fin, a small mouth, and a protractile snout. They are widely distributed, but, being deep-sea fishes, are nowhere found in abundance.

Ribbons. Narrow-painted streaks on a ship's side. The tatters of a sail blown away.

Richmond, the capital of Virginia, and a port of entry, is situated on the north bank of the James River, at the head of tide-water, in lat. 37° 32′ 17″ N., lon. 77° 27′ 28″ W. There are regular lines of steamers to New York, Philadelphia, and Baltimore, and it has admirable railroad facilities. Vessels drawing 16 feet of water can come to Rocketts, at the lower end of the city; the dockage capacity is large. The James River and Kanawha Canal extends from Richmond to Buchanan, a distance of 210 miles. There are 523 manufacturing establishments in the city, embracing 43 plug- and smoking-tobacco factories, 40 cigar-factories, flour- and paper-mills, etc. Pop. 75,000.

Rickers. Lengths of stout poles cut up for the purpose of stowing flax, hemp, and the like. Spars supplied for boats' masts and yards, boat-hook staves, etc.

Ricochet. See FIRE.

Riddle. A kind of weir.

Ride. To lie at anchor; to be supported on the water. A rope *rides* when the part on which the strain is brought lies over and jams the other parts. *To ride down*, to force anything, as a yard, or bunt of a sail, down to its proper place by throwing the weight upon it.

RIDING-BITTS. The bitts to which the cables are secured.

Riders. Interior ribs, to strengthen and bind the parts of a ship together; they are fayed upon the inside planking and bolted through all, and are placed where they are most needed, either at the bow or the stern of the ship. Also, the upper tiers of casks.

Ridge-rope. The centre-rope of an awning. The rope to which the edges of an awning are hauled out.

Rifle. See ORDNANCE.

Rig. The disposition of the masts and yards, the cut of the sails, and manner in which spars, sails, and rigging are fitted. To fit the shrouds, stays, braces, etc., to their respective masts, yards, etc. To cod; to play a sportive trick upon. *To rig out* (or *in*), to run a boom out (or in).

RIGGERS. Men employed in navy-yards to fit the rigging of all ships before being put in commission.

RIGGING. A general name for all ropes or chains employed to support and work masts, yards, sails, etc. *Standing rigging*, rigging set up permanently, as stays, backstays, bobstays, shrouds, etc. *Running rigging*, the ropes which are hauled upon from time to time, in order to adjust the yards, sails, etc.

RIGGING-LOFT. A large room where rigging is stretched, cut, served, etc., in readiness to be sent to ships.

RIGGING-MAT. A heavy mat seized upon the standing rigging to prevent its being chafed.

RIGGING-SCREW. A machine employed to force the two parts of a stiff rope together in order that a seizing may be put on; as, in turning in dead-eyes, forming the eyes of shrouds, etc.

RIGGING-STOPPER. See STOPPER.

Riga, a commercial port of Russia, is situated on the Düna, in lat. 56° 57′ N., and lon. 24° 6′ 30″ E. Along the river on both sides are spacious quays. The inner harbor does not admit vessels drawing more than 15 feet of water; large ships load and unload outside of the bar at the mouth of the river, where is the custom-house. Grain, flax and flaxseed, hemp, wool, hides, tallow, timber, and spars are the chief exports. Pop. 99,000.

Rigel. The star β *Orionis*.

Right. Directly; as, right ahead, right abeam, etc. A ship is said *to right* when she returns to a perpendicular position after having been listed over by the force of the wind. *To right the helm*, to put it amidships.

Right Ascension (Lat. *rectus*, right, straight; *ascensio*, rising). The right ascension of a heavenly body is the arc of the equinoctial intercepted between the first point of Aries and the circle of declination passing through the centre of the body. It is reckoned from the first point of Aries eastward, from 0° to 360°, or from 0 to 24^h. Right ascension and declination are the equinoctial co-ordinates for determining positions on the celestial sphere.

RIGHT ASCENSION, CIRCLES OF. See CIRCLE.

Right-handed Rope. Rope laid up with the sun. See ROPE.

Right Sailing. Running a course on one of the four cardinal points, so as to alter only a ship's latitude, or longitude.

Right Whale. See WHALE.

Rill. A very small run of fresh water, less than a rivulet.

Rimbase. The short cylinder at the junction of the trunnion with the gun.

Rime. Hoar-frost; condensed vapor.

Ring. Anything in the form of a circle. An old brass instrument for measuring altitudes of heavenly bodies, having an aperture in one side, through which a ray entering indicated the altitude on the graduated surface opposite. See SATURN, ANCHOR.

RING-BOLT. A bolt with an eye in one end in which a ring is fitted for convenience in hooking tackles.

RING-DOGS. Iron implements used in hauling timber. They are formed by putting a ring through the eyes of two common dogs.

RING-ROPE. A rope used, in bending a chain, to haul the end of the chain up to the ring of the anchor.

RING-STOPPER. See STOPPER.

Ring-tail. A sail set, like a stun'sail, beyond the leech of a sail spread by a gaff and boom.

RING-TAIL BOOM. A boom extending beyond the spanker-boom or main-boom, to spread a ring-tail.

Rio de Janeiro, the largest and most important city of South America and the capital of Brazil, is situated on the west side of the Bay of Rio de Janeiro, in lat. 22° 54′ 7″ S., lon. 43° 9′ W. Its port, which is large and deep, is defended by a castle. The principal edifices are the palace, the naval and military arsenal, and public hospital. Its imports comprise the product of every country. Its chief exports are cotton, sugar, coffee, rum, gold, diamonds, topazes, amethysts, and aquamarine. The bay is 17 miles long and 11 miles wide, and forms one of the finest harbors in the world. Pop. 275,000.

Rip. A pannier or basket used for carrying fish. See TIDE-RIP.

RIPPERS. Men from the sea-shore, who sell fish to the inland towns and villages.

Riparia. A law-term for the water running between the banks of a river.

Ripary. Inhabiting the sea-shore.

Ripping-iron. A calker's tool for tearing oakum out of a seam, or stripping copper or sheathing from a ship's bottom.

Ripple. The small waves raised on the surface of the water by the passage of a light breeze.

RIPPLE-MARKS. The ripply appearance left at low-water on the flat part of a sandy beach.

Risberm. Fascines placed to oppose the violence of the surf.

Rising. A term derived from the shape of a ship's bottom in general, which gradually narrows or becomes sharper toward the stem and stern-post. On this account it is that the floor of a ship toward the extremities is raised or lifted from a level line, otherwise the shape of the timbers would be so very acute as not to be procurable in wood, or the timber would be so grain-cut as not to be of sufficient strength. Also, the narrow strake just below the thwarts of a boat.

RISING-FLOOR. The floor-timbers forward and aft, on account of the narrowing of the ship's body, are gradually lifted or raised upon the dead-wood or rising-wood, and are known as *rising-floors.* They are difficult to obtain in wood from their acute-angled shape.

RISING-LINE. An elliptical line drawn upon the sheer-plan to determine the sweep of the floor-heads throughout the ship's length.

RISING-SQUARE. A square used in the molding of the ship's frame, upon which is marked the rising of each floor at a sirmark, as well as the half-breadth at the same point to which spots the molds are applied for the molding of the floors.

RISING-WOOD, or DEADWOOD. The wood placed upon the top of the keel at the ends of the ship upon which the cants are secured, where there is so much rise to the floors that it is difficult to obtain timbers to cross the keel. The rising-wood is introduced in order to lessen the expense, and also to continue the framing of the ship to the stem and stern-post. As the ship becomes sharper more rising-wood becomes necessary.

Risks. The casualties against which insurances are made on ships and cargoes.

Rittoch. A name for the tern, *Sterna hirnudo.*

Rive. The sea-shore.

River-risk. A policy of insurance from the docks to the sea.

Rivers. A river is a natural stream of water flowing through the land. Small rivers are called creeks, and still smaller streams are named brooks, rills, and rivulets. The ground through which a river flows is its bed; the deepest part the channel, and the country drained by it is its basin. Rivers have their origin in lakes, from natural springs, and in mountains, some from the melting snows, others issuing from glaciers. Such beginnings are sources, or heads. Rivers empty into the ocean, or into one of its arms, or they stop in some inland lake, flow into some other river, or are lost in desert sands or arid wastes. The final termination of a river is its mouth, and when there are more than one, it is called a delta. Rivers are oceanic; that is, their waters reach the ocean; or they are continental; that is, they are lost in some lake, desert, or waste. Most of the larger rivers are oceanic, but many continental rivers of considerable size exist. A river flowing into another is a tributary, or branch, and rivers are affluents of the bodies into which they empty their waters. Confluent streams are those flowing into the same waters.

Some continental rivers become oceanic after great rains, as the Mareb, in Abyssinia. When a river falls over a gradual descent, such a place is called the rapids, and when the fall is sudden, it becomes a cataract or fall. Many such descents occur and interrupt navigation, more or less, according to their character. The greatest falls are those of the St. Lawrence, at Niagara, the stream, 800 feet wide, here falling over a precipice 165 feet high, and gradually wearing a bed 200 feet deep. The highest fall is found in the Himalaya Mountains. Such rapids and falls (and shoals and rocks) often interrupt navigation in rivers of considerable size. Rivers are usually fresh, but such as have a tidal flow are salt as far as the tide reaches. The tidal-wave, when it meets the current of rivers, sometimes carries a wave called a *bore* to some distance above its mouth. The principal one is in the Amazon. Many rivers flow underground during a part of their course, and some are suddenly lost in the ground. Sometimes rivers lose a part of their waters through narrow connecting channels, known as bayous in Louisiana, and as shats in Persia. Many rivers periodically overflow their banks, as the Ganges, Indus, and Nile.

The following table exhibits the lengths of the chief rivers:

Rivers of the World.

Name.	Miles.	Name.	Miles.
Amazon	4700	Red	2000
Mississippi	3200	Parana	2000
Mississippi and Missouri.	4500	St. Lawrence	2000
Yangtze-Kiang	3300	St. Lawrence proper	600
Nile	3200	Niger	2000
Hoang-Ho	3200	Euphrates	1600
Obi	3000	Danube	1800
Irtish	2000	Apurrimas	1800
Yenesei	2600	Ganges	1800
Tungouska	2300	Rio Grande	1700
Missouri	2200	Indus	1700
Burramapootra	2200	Orinoco	1600
Volga	2200	Platte	1600
Arkansas	2150	Columbia	1506

Name.	Miles.	Name.	Miles.
Dnieper	1300	Rhine	800
Paraguay	1200	Peace	800
Yellowstone	1100	Elbe	700
Kansas	1100	Alabama	600
Mackenzie	1100	Appalachicola	600
Blue Nile	1000	Tagus	600
Ohio	1000	Oder	600
Dwina	1000	Cumberland	600
Don	1000	Susquehanna	500
Senegal	1000	Savannah	500
Magdalena	1000	Rhine	500
Snake	1000	Illinois	500
Gara	1000	Po	450
Tigris	1000	Seine	400
Jumna	900	Connecticut	400
Tennessee	900	Garonne, Delaware, and St. John, each	350
Cauca	800		

A few of these rivers merit an especial mention. The Amazon, also called the Marañon, and, from its discoverer, the Orellana, is formed by the union of the Tunguragua and Ucayale,—the former rising in a lake in Peru, the latter formed by the Apurimac and Payo. It has many islands, some of them 10 miles in circumference, is navigable for 2000 miles, and its mouth is 180 miles wide. The tides extend 400 miles, and the *bore* is 10 to 15 feet high. Besides the branches mentioned, the Napo, Yapara, Negro, Yutay, Madeira, and Xingu, are the chief ones. The Madeira is 1800 miles long. The basin drained by the Amazon embraces 2,400,000 square miles. Its head-waters connect with those of the Orinoco. It was discovered by Vincent Yanez Pinzon in 1500, and Orellana, in 1539, traced its course. It was thoroughly described and explored by Condamine in 1743, and by Humboldt, Lieut. Herndon, and lately by Commander Selfridge, in the "Enterprise."

The Mississippi rises in a small lake (Itasca) in Minnesota, although a dozen other lakes might as easily be named as its source, and flows nearly in a straight line south to the Gulf of Mexico, pouring its waters out through five mouths, called here passes. It has scores of tributaries, four of them at least being large rivers, and a dozen others of some size.

The Yangtze-Kiang and the Hoang-Ho are both large rivers of China. They rise nearly together in the table-lands of Chinese Thibet, the former flowing southeast, the latter northeast, until they are 1000 miles apart, when they turn towards each other, and finally empty their waters into the Yellow Sea, 100 miles apart. The alluvium brought down by these rivers gives the name to the Sen and Yellow Rivers, and has sensibly decreased the depth of the former. The Yangtze-Kiang receives the several names of Minachoo, Ya Loong, Tachoong, Kin Sha, and Ta Kiang, in portions of its course. It has 7 large tributaries, and is navigable for 1000 miles.

The Obi, Yenesei, and Lena are mighty streams, rising in the centre of Asia, and flowing in a northerly direction into the Arctic Ocean. Each has numerous tributaries, and together they water and drain the vast steppes of Siberia. Although deep and wide, these rivers are navigable only a small portion of the year because of the ice. Each drains 1,000,000 square miles of territory.

The other large rivers of Asia, the Ganges, Indus, Burramapootra, and Euphrates, flow through low and marshy districts, and at certain seasons overflow their banks, rendering the lands fertile.

The Nile is one of the most remarkable rivers of the world. Its source, but recently ascertained, is in the Lakes Albert and Victoria Nyanza, in the interior of Africa. It flows nearly north to the Mediterranean, pouring its water through five mouths,—the original *delta*. It receives one large tributary, the Blue Nile, and several smaller ones, but for the last 1300 miles receives none,—a solitary instance of such a lack. It periodically overflows its banks, not only watering an arid valley, but fertilizing it by the quantities of mud there deposited. In its course it traverses the ancient countries of Egypt and Nubia, where still exist gigantic remains of the first civilization of the globe.

The Volga is the largest river of Europe. It rises nearly in the centre of Russia, and empties into the Caspian Sea. During the lower part of its course it has many bayous or canals. The Danube is next, and the Dnieper, Dwina, Don, and Rhine are not far behind it in size and importance.

Arabia and the Great Sahara Desert of Africa are most destitute of rivers, and the whole western coast of South America is without rivers of any size, none of them being navigable.—*F. S. Bassett, Lieutenant U.S.N.*

Rivet. The roe of a fish. A pin or bolt of metal for confining pieces of material together; the ends are enlarged in diameter and formed into heads, projecting over and clasping the outer surfaces of the united pieces by battering or longitudinal compression.

Roach. The curvature of the foot of a sail; the object is to keep the foot from chafing. A gregarious fresh-water fish of the carp family (*Leuciscus rutilus*). It is of a silver-white color, with a greenish back, having the dorsal fin opposite the ventral. It is about a foot in length.

Road, or Roadstead. An off-shore anchorage, affording less protection to vessels than a harbor.

Roader, or Roadster. A term applied to a clumsy vessel which works its way from port to port by means of the tides, anchoring when wind and tide are unfavorable.

Roast Beef Dress (*Eng.*). Full uniform; probably from its resemblance to that of the royal beef-eaters.

Roast Beef of Old England. A popular air by which officers are summoned to the dinner-table.

Robans. Short bits of spun-yarn, foxes, etc., for securing the head of a sail to the jack-stay on the yard.

Rochester, a port of entry in Monroe County, N. Y., is situated on both sides of the Genesee River, in lat. 43° 8′ 17″ N., lon. 77° 51′ W. The city is connected by a net-work of railways with every city of importance in this country and Canada, and it has also two important channels of trade in the Erie and Genesee Valley Canals. The foreign commerce, chiefly carried on by the lakes, although some of it comes by way of New York, is quite large, and its domestic trade is much larger. It is one of the greatest flour-producing cities in the world, and also has extensive manufactories of other kinds. The largest carriage-factory in the United States is located here. There are 16 flour-mills, grinding each year an average of 3,000,000 bushels of wheat. Pop. 82,000.

Rock. *Half-tide rock*, a rock awash at half-tide.

Rock-cod. A species of cod found on a rocky bottom.

Rocket-boat. A flat-bottomed boat fitted with rocket-frames to fire Congreve rockets from in naval bombardment.

Rock-fish. A salt-water fish, a species of goby, *Gobius niger*.

Rock-hind. A large fish of tropical regions, *Serranus catus*.

Rockling. A fish of the genus *Motella* (*M. vulgaris*), belonging to the cod family; whistle-fish.

Rock-scorpion. A name applied to persons born at Gibraltar.

Rock-shaft. In mechanism, a shaft which oscillates about its axis; as, in transmitting the reciprocating motion from the eccentrics to the valves of a steam-engine.

Rodding-time. The season for fish spawning.

Rodgers, C. R. P., Rear-Admiral U.S.N. Born November 14, 1819, in Brooklyn, N. Y. Appointed midshipman from Connecticut, October 5, 1833; attached to frigate "Brandywine" and sloop "Vincennes," Pacific Station, 1834–36; navy-yard, New York, 1837; sloop "Fairfield" and brig "Dolphin," Brazil Squadron, 1837–39.

Promoted to passed midshipman, July 8, 1839; schooner "Flirt," coast of Florida, 1839–40; and in command of schooner "Phœnix," 1841–42, being actively employed in the Seminole war during those three years; sloop "Saratoga," coast of the United States, 1842–43.

Commissioned as lieutenant, September 4, 1844; served in Mediterranean Squadron in frigate "Cumberland," 1843–45, and in store-ship "Lexington," 1845; coast survey, 1846; frigate "Potomac" and sloop "Albany," blockading Mexican coast, 1847; present and in the trenches at the reduction of Vera Cruz and at the capture of Tabasco and Tuspan; coast survey, 1848–49; frigate "Congress," Brazil Squadron, 1850–51; frigate "Constitution," coast of Africa, 1852–55; coast survey, commanding steamer "Bibb" and schooner "Gallatin," 1856–57; steam-frigate "Wabash," Mediterranean Squadron, 1858–59; commandant of midshipmen at Naval Academy, 1860–61.

Commissioned as commander, October 15, 1861; served in steam-frigate "Wabash" as captain and fleet-captain, 1861–63, commanding that ship at the battle of Port Royal, November, 1861, and the naval force in the trenches at the reduction of Fort Pulaski, January 27, 1862. While in the "Wabash," much employed on detached service, in command of a division of gunboats in retaking the coast and inlets of Georgia and Florida, and South Carolina south of Port Royal; fleet-captain in the "New Ironsides" in the attack on Charleston, April 7, 1863. Rear-Admiral Dupont in his official report of that engagement says, "On this, as on all other occasions, I had invaluable assistance from the fleet-captain, C. R. P. Rodgers, who was with me in the pilot-house directing the movements of the squadron. For now over eighteen months in this war this officer has been afloat with me, and in my opinion no language could overstate his services to his country, to this fleet, and to myself as its commander-in-chief." Commanded steam-sloop "Iroquois," 1863–65, on special service.

Commissioned as captain, July 25, 1866; navy-yard, Norfolk, 1865–67; commanded steam-frigate "Franklin," Mediterranean Squadron, 1868–70.

Commissioned as commodore, August 28, 1870; special service in Europe, 1871; chief of Bureau of Yards and Docks, October, 1871–74.

Commissioned as rear-admiral, June 14, 1874; superintendent Naval Academy, 1874–78; commanding Pacific Station, 1878–80.

Rodgers, John, Commodore U.S.N. Born in Hartford County, Md., 1771; died at Philadelphia, August 1, 1838. Entering the navy as a lieutenant, March 9, 1798, he was the executive-officer of the frigate "Constellation," Commodore Truxtun, when she captured the French frigate "L'Insurgente" off Nevis, February 9, 1799, and took possession of the prize. Made a captain March 5, 1799, he cruised in the "Maryland," 20, upon the West India Station; in 1802 he commanded the "John Adams," 28, with which and the "Enterprise," 12, he successfully attacked, in June, 1803, a Tripolitan cruiser of 22 guns, and several gunboats at anchor near Tripoli; in 1804 he commanded the "Congress," 38, in the squadron employed against Tripoli under Commodore Barron, whom, in 1805, he succeeded in the command. After the peace with Tripoli, he proceeded with his squadron to Tunis, where he engaged in negotiations which resulted in the establishment of friendly relations. In the spring of 1811, in the "President," 44, off Annapolis, he heard that a seaman had been impressed off Sandy Hook by an English frigate; sailing for that point without delay, May 16 he hailed, about 8½ P.M., a vessel of war, but received no answer. After a little delay, the stranger hailed, and immediately fired a shot that entered the "President's" mainmast. After a short engagement, in which his opponent was much crippled, he ceased firing, and on the following morning boarded, discovering her to be H.B.M. ship "Little Belt," 22 guns, Capt. Bingham. The accounts given by the two commanders of this affair differed materially, particularly as to the firing of the first gun; and it widened the breach which already existed between the two nations. June 21, 1812, receiving official intelligence of the declaration of war against Great Britain, Commodore Rodgers sailed from New York in command of a squadron; June 23, while chasing the British frigate "Belvidere," during a running fight, a gun burst, killing and wounding 16, Commodore Rodgers being among the latter; in a subsequent cruise he took the British packet "Swallow," with a large amount of specie, and the schooner "Highflyer"; appointed June 14 to the new frigate "Guerriere," he rendered important service in the defense of Baltimore; from April, 1815, to December, 1824, he served as president of the Board of Navy Commissioners; Acting Secretary of the Navy, September to December, 1823; and in 1824–27 in command of the Mediterranean Squadron. On his return he was again on the Board of Navy Commissioners, which position he relinquished in 1837.

Rodgers, John, Rear-Admiral U.S.N. Born in Maryland, and appointed midshipman from District of Columbia, April 18, 1828. Attached to frigate "Constellation," Mediterranean Squadron, 1829–32; Naval School, Norfolk, 1833–34.

Promoted to passed midshipman, June 14, 1834; on leave, 1835; brig "Dolphin," Brazil Squadron, 1836–38; special service, 1839.

Commissioned as lieutenant, January 22, 1840; brig "Boxer," Home Squadron, 1841–43; special service, 1844–45; sloop "Marion," Mediterranean Squadron, 1846–47; coast survey, 1848–52; commanding steamer "John Hancock" and Surveying and Exploring Expeditions to North Pacific and China Seas, 1853–56.

Commissioned as commander, September 14, 1855; special duty, Washington, D. C., 1857–59; waiting orders, 1860.

In 1861, Commander Rodgers was ordered to special duty in the West, superintending the construction of the Benton class of ironclads. In 1862 he was assigned to the command of the ironclad steamer "Galena," and ordered to the North Atlantic Blockading Squadron. On May 10, 1862, Commander Rodgers left Hampton Roads in command of an expedition of gunboats, with orders to enter the James River, and, if possible, to ascend the river to Richmond. After two engagements with rebel batteries, which were in each instance silenced, the fleet reached Fort Darling, a casemated battery erected on the crest of a hill, which, together with sunken vessels, effectually obstructed the channel.

On the morning of May 15, Commander Rodgers anchored the "Galena" in front of and at a distance of 500 yards from the rebel fort. The "Aroostook" and "Port Royal," wooden gunboats, were stationed 800 yards below the flagship. At 8 A.M. the vessels opened fire on Fort Darling, and from that time until 12 M. kept up a vigorous bombardment. At 12.10 P.M., Commander Rodgers having expended every shot and shell in the magazine and shell-room of the "Galena," made signal to withdraw from action, the vessels retiring in good order, and giving the rebels a parting shot as they steamed down the river. The monitor being unable to give sufficient elevation to her guns, and the "Naugatuck," better known as the Stevens battery, having burst her rifle-gun at the first fire, were rendered useless so far as the fort was concerned, although both vessels did good service during the action by stationing their crews as sharpshooters and picking off the rebel riflemen who greatly annoyed the crews of the wooden vessels.

The armor of the "Galena" did not prove of any service to her. She was hit 129 times, losing in killed and wounded two-thirds of her crew. The "Aroostook" and "Port Royal" suffered to a less extent.

Commissioned as captain, July 16, 1862.

In 1863, Capt. Rodgers was ordered to the command of the monitor "Weehawken," and sailed from New York in that vessel for the South Atlantic Blockading Squadron. On his way South, and while off the Delaware Breakwater, he encountered a heavy gale. He was urged to run in and remain until the storm abated. This he declined to do, saying he wished to test the sea-going qualities of the monitors. The "Weehawken" rode out the gale and reached Port Royal in safety.

On June 17, 1863, in Warsaw Sound, Ga., Capt. Rodgers, in the "Weehawken," encountered the powerful rebel ironclad "Atlanta," a vessel of much greater tonnage than the "Weehawken." So confident were the rebels of a speedy victory, that the "Atlanta" was accompanied from Savannah to the scene of action by boats freighted with gay parties eager to witness the triumph of their vessel. Five shots were fired by the "Weehawken." The fight lasted but 15 minutes, at the end of which time the "Atlanta" surrendered. An important feature of this conflict was the final settlement of the dispute as to the value of the new 15-inch gun, which fully proved its merit.

Commissioned as commodore, June 17, 1863; commanding ironclad "Dictator," special service, 1864–65; commanded monitor "Monadnock," 1866–67; and in that vessel made the passage around the Horn to San Francisco. Commodore Rodgers touched at Valparaiso, and witnessed the bombardment of that place by the Spanish fleet.

Commanding navy-yard, Boston, 1867–69.

Commissioned as rear-admiral, December 31, 1869; commanding Asiatic Fleet, 1870–72; commandant Mare Island Navy-Yard, 1873–77; superintendent Naval Observatory since May 1, 1877.

Rodman Gun. See ORDNANCE.

Rodney, George Brydges, Lord, was the son of Capt. Rodney, who having won the favor of George I. as the commander of the royal yachts, the king gave his son a "letter of service," and at the early age of 12 he went to sea. In 1739 he was promoted to lieutenant; post-captain in 1742, and commander of the Newfoundland Station, with the rank of commodore, in 1748. In 1752 he returned home, and was elected a member of Parliament. He afterwards commanded the "Fouguex," the "Prince George," and the "Dublin" men-of-war. In 1759 he was promoted to rear-admiral. In July of that year he bombarded Havre for 3 days, destroying the town and fortifications. In 1761 he took Martinique, Grenada, and Santa Lucia. In 1762 he became vice-admiral, and in 1764 was made a baronet. In 1779 Spain and France joined in war against England. The siege of Gibraltar was undertaken, and Rodney was ordered to the West India Station with 22 sail of the line and 8 frigates, and was also ordered to relieve Gibraltar *en route.* After capturing 7 Spanish ships of war he fell in, January 16, 1780, with Admiral Langura off Cape St. Vincent. Of the Spanish fleet 5 were captured and 2 destroyed. After this action he sailed for the station of his command, and on the 17th of April he defeated, near Martinique, the French fleet under the Count de Guichen. After this Rodney took Eustatia from the Dutch, with 250 ships and other booty. Demerara and Essequibo next surrendered. On April 12, 1782, together with Hood and Drake, he encountered the French fleet under De Grasse off Dominica. Each fleet consisted of 30 ships of the line. The fight lasted 12 hours, when De Grasse retired totally defeated. The English loss was 7 ships and 2 frigates, and 600 men, while the French casualties were 3000 killed, 6000 wounded, and a train of artillery besides their ships. Count De Grasse was himself taken prisoner. For this great victory, which saved Jamaica, ruined the naval power of Spain and France, and gave the finishing blow to the war, Rodney was elevated to the peerage as Baron Rodney, and received a pension

of £2000 per annum for himself and his successors. He lived in retirement the rest of his life, and died May 21, 1792.

Roger. The black flag hoisted by pirates.

Roger's Blast. A sudden and local motion of the air resembling a whirlwind.

Rogue's March. The tune appropriated to drumming a bad character out of a ship or out of a regiment.

Rogue's Yarn. A yarn which differs from the other yarns in a rope. It is twisted the contrary way, or is different in color or material. The object is to detect the theft of government rope.

Roll. The oscillating movement of a ship caused by the seas striking on her side. Under the same circumstances of wind and sea the roll depends on the position of the centre of gravity, the construction of the ship, and the amount and kind of sail carried. If the centre of gravity is too low, the roll is short and jerky, and there is danger of carrying away the masts; if too high, there is danger of capsizing; if in the proper place, the roll is long and deep, but easy, the ship coming to her bearings gradually.

ROLLING-CHOCKS. The jaw-pieces fitted to a yard.

ROLLING-ROPE. A rope used on a light yard to support it in heavy rolling. See ROLLING-TACKLE.

ROLLING-TACKLE. A tackle from the quarter of a lower or topsail yard to the mast, to steady the yards in heavy rolling. It is also used on the opposite quarter of the yard in taking in a heavy weight, to take up a portion of the thrusting strain. With jaws or patent trusses rolling-tackles are seldom used.

Roller. A heavy oceanic swell setting in upon the coast. In mechanism, a piece having a circular transverse section, placed between a moving and a fixed body to avoid sliding contact and its consequent friction. It may have the form of either a cylinder, cone, or sphere. Cylindrical rollers are used for motion in a plane perpendicular to their axes; and conical or spherical rollers for angular motions, as in receiving the axial thrust of a shaft.

ROLLING-SWELL. That heaving of the sea where the waves are very distant, forming deep troughs between.

Roman Cement. A cement which hardens under water; used for piers, docks, etc.

Rombowline. See RUMBOWLINE.

Ronckendorff, William, Commodore U.S.N. Born in Pennsylvania. Appointed from Pennsylvania, February 17, 1832; attached to the schooner "Experiment," on the coast, and transferred to the schooner "Porpoise," West India Squadron, 1832–33; frigate "Constitution" and sloop "John Adams," Mediterranean Squadron, 1835–37.

Promoted to passed midshipman, June 23, 1838; brig "Consort," coast survey, 1839–41; sloop "Preble," Mediterranean Squadron, 1842–43.

Commissioned as lieutenant, June 18, 1843; frigate "Congress," Brazil Squadron, 1843–45; 1845, bearer of dispatches, by the way of the Isthmus of Panama, to the commander-in-chief of the Pacific Squadron, and served in that squadron during the Mexican war, returning to New York from that station in the frigate "Savannah," September, 1847; sloop "Portsmouth," coast of Africa, 1849–51; receiving-ship, New York, 1852; frigate "Cumberland," Mediterranean Squadron, 1852–55; navy-yard, Philadelphia, 1855–58; commanding steamer "M. W. Chapin," Brazil Squadron and Paraguay Expedition, 1859; attached to coast survey, 1860.

Commissioned as commander, June 29, 1861; on February 28, 1861, Commander Ronckendorff was ordered to take command of the steamer "Water-Witch," and proceeded to the Gulf Squadron, on special service, until October 12, 1861, at which date he was detached and ordered to proceed North as bearer of important dispatches to the Hon. Secretary of the Navy, from Flag-Officer McKean; December 27, 1861, ordered to the steam-sloop "San Jacinto," and on March 4, 1862, ordered to proceed with that vessel in search of the ship-of-the-line "Vermont," supposed to be on George's Shoals; March 8, returned to Boston Navy-Yard, and on the following day ordered to proceed to Hampton Roads with the "San Jacinto," with greatest dispatch, and report to the senior officer present, to watch and attack, if necessary, the Confederate steamer "Merrimac"; May 15, 1862, participated in the attack on the fortifications on Sewell's Point; May 18, 1862, proceeded to Norfolk with the "San Jacinto"; May 23, 1862, sailed from Hampton Roads to Key West with Flag-Officer Lardner on board; August 1, 1862, returned North with the "San Jacinto," by order of flag-officer,—having yellow fever on board; September 29, 1862, ordered to join the North Atlantic Squadron with the "San Jacinto," and to proceed off Wilmington, N. C.,—blockading; October 9, 1862, ordered to return from Wilmington with the "San Jacinto" to Hampton Roads; October 26, 1862, ordered to proceed in the "San Jacinto" to Bermuda, and cruise among the West India Islands in search of the rebel steamer "Alabama"; May 26, 1863, detached from the "San Jacinto," and reported for the command of the steam-sloop "Ticonderoga"; May 28, 1863, ordered to the West Indies, in the "Ticonderoga," as flag-ship of that squadron, under Rear-Admiral Lardner, to look after the rebel cruisers; September 28, 1863, ordered to Philadelphia in the "Ticonderoga" for repairs; October 16, 1863, detached from the "Ticonderoga" and ordered to the command of the frigate "Powhatan," and to proceed to the West Indies as flag-ship of that squadron; October 14, 1864, detached from the command of the "Powhatan,"—she having returned home; October 18, 1864, ordered to report to Rear-Admiral Gregory, at New York, for special duty; was ordered West on a court of inquiry, held at Erie, Chicago, Cincinnati, Louisville, Ky., and then returned to Philadelphia; February 15, 1865, ordered to command the ironclad "Monadnock," up the James River,—was there until the evacuation of Richmond,—came down the river and anchored off Fortress Monroe to look out for the "Stonewall"; in May, sailed in the "Monadnock," in a squadron commanded by Admiral Godon, to Havana, in search of the "Stonewall"; July 9, 1865, transferred from the ironclad "Monadnock" to the ironclad "Tonawanda," and, after a short cruise in her, was detached, she being laid up, and ordered to command the receiving-ship at Philadelphia, January 1, 1866; Commander Roncken-

dorff was actively employed during the whole period of the Rebellion; in charge of ironclads, New Orleans, 1871–72.

Commissioned as commodore, 1873. Retired November 9, 1874.

Rood-goose. A name for the brent-goose.

Rooke, Sir George, a distinguished British admiral, was born in 1650, near Canterbury. At the age of 30 he was a post-captain, and in 1689 was promoted to rear-admiral. He was engaged in the action off Beachy Head, between the Earl of Torrington and the French Admiral De Tourville, and in 1692 he took part in the memorable battle of La Hogue. On this occasion, for his dashing and brilliant services, he received the rank of vice-admiral of the red, the honor of knighthood, and a pension of £1000 per year. His next service of importance was the destruction of a Spanish plate fleet in the port of Vigo; and in July, 1704, in conjunction with Sir Cloudesley Shovel, he captured Gibraltar. On August 9 of the same year he fought off Malaga a vastly superior French fleet under the Comte de Toulouse, and although the English fleet won the battle, the victory was a barren one, as the French fleet escaped. Upon Sir George's return he was received with marked distinction by Queen Anne; but the government being hostile to him, he resigned his positions, and until his death on the 24th of January, 1709, he lived in retirement on the family property in Kent.

Rooke, or Rouke. A mist, dampness, or fog.

Room, Roomer, or Going Room. An old term for going large. *To go room*, to bear up.

Room and Space. The space occupied by each frame of the ship, or the distance of the frames from centre to centre.

Roost. A phrase applied to races of strong and furious tides which set in between the Orkney and Shetland Islands, as those of Sumburgh and the start.

Rope. "A large stout twisted cord of not less, usually, than an inch in circumference. It differs from cord, line, and string only in its size." (Webster.)

The different kinds of rope are designated by the material of which they are made, by the peculiarities of their manufacture, by their sizes, number of strands of which they are composed, and by the various uses to which they may be adapted.

Plain-laid rope is made by laying three strands together right-handed, or from left to right.

Cable- or *hawser-laid rope* consists of 9 strands, and is made by laying 3 plain-laid ropes together left-handed, or from right to left.

Cable-laid stay consists of 12 strands or 4 plain-laid ropes, closed as above, to form a single rope.

Shroud-laid rope is made by laying 4 strands together right-handed, and takes its name from the use to which it is generally applied. It is usually made with a heart to fill up the space in the centre of the strands, which assists in keeping them in place when subjected to a heavy strain.

Back-handed rope is made by twisting each strand right-handed, or in the same direction as the yarns, and laying the strands together left-handed.

The materials from which rope is principally manufactured are hemp, or the fibre of the cultivated hemp plant, abaca, or manilla, which is the fibre obtained from a species of banana found in large quantities in the Philippine Islands, hide, and wire.

In some localities, rope of an inferior quality is made from cotton, coir, or the fibre obtained from the cocoa-nut palm, and jute, which resembles hemp, but has less strength and durability.

The hemp used for rope in the United States is principally of native growth or imported from Russia. An article of superior value is produced in Italy, but it is less used for the manufacture of cordage than for other purposes. The quality of the fibre varies considerably with the climate and soil in which it is raised, experiments showing that the average breaking strain of rope-yarns No. 20 for a strand of 3-inch rope, made from the different kinds of hemp, are as follows: Italian, 157 pounds; Russian, 153 pounds; American, 141.5 pounds.

The fibre is prepared for use by a process called *retting* or *rotting*, which consists in placing the stalks in water until fermentation takes place. By this means the glutinous matter which binds the fibre to the woody portion of the stalk is set free. The same result is sometimes obtained by exposing the stalks to dew and rain, and the process is then called *dew-rotting*, but a longer time is required than by the former method.

The stalks, having been rotted and dried, undergo the process of *breaking*, by which they are cracked by repeated blows, and the brittle, woody portion separated from the fibre, which falls away when beaten with a broad wooden blade in the process of *scutching*.

The hemp is further prepared for spinning by the operation of *hackling*, which consists of drawing a bunch of the fibre through a set of long, sharp steel points placed in an upright position, for the purpose of straightening it and removing the tow, or shorter fibre of less value, and dust. The tow which is thus separated is sometimes used in the manufacture of inferior qualities of rope.

Hackling is also done by means of a machine consisting of a revolving drum armed upon its surface with steel points, which, gradually increasing in length, separate the tow from the more valuable fibre.

The hackled hemp is then passed through the spreader, by which it is again combed and straightened by the teeth attached to the endless chain of hackle-bars, and leaves this machine in a loose strand of fibre called a roping or sliver. Several of these ropings are then subjected to a similar operation in a machine called the drawing-frame, by which they are formed into a smoother and more regular roping of the size required for spinning the yarn. The ropings, which coil themselves into large tin boxes or cylinders as they come from the drawing-frames, are then taken to the jennies for spinning.

The spinning-jenny consists of an iron frame of rectangular shape, about 12 feet long and 4 feet high, and varying in width from 2 to 3 feet. The roping is drawn from its box, which is placed at the end of the jenny, by an endless chain of gill-bars, and carried to the mouth-piece, a flat metallic plate placed in an upright position.

Connected with the mouth-piece is an attachment for regulating, automatically, the speed of the gill-bars according to the size of the roping, so as to make a yarn of uniform size. The rop-

ing next passes between two calender rollers, tongued and grooved, and lastly through the flyer, by which it is twisted, and is wound upon the bobbin placed between the arms of the flyer.

The yarns next undergo the process of tarring by placing a number of the bobbins in frames at one end of the tarring-room, and leading the yarns through a guide-plate into a large trough filled with tar heated to a temperature of about 200° F. The yarns, after leaving the tar, pass through holes in another plate, by which the tar is scraped off, and from thence between nipper-rollers, which presses them dry, and are wound upon bobbins at the other end of the tarring-room ready for the final processes of the rope-walk.

The bobbins are again placed in upright frames at the end of the rope-walk, the ends of as many yarns as are required to form the strand are passed through the register-tube into which they fit closely, and are fastened to one of the hooks on the face of the hauling-down machine. This machine runs upon a track the length of the rope-walk. The same band by which it is propelled carries the machinery for turning the hooks to which the strands are attached, and the machine, traveling away from the bobbins, draws the yarns through the register-tube and twists them into strands.

The laying of the strands is performed by two machines called the upper and lower layers, the former traveling on a track as required, and the latter being stationary. Each strand is attached to a separate hook on the lower layer, and all of the strands for the same rope are fastened to the same spindle on the upper layer, each strand being twisted while the rope is laid by the upper layer. A wooden frame called the top-sled travels on tracks overhead, and supports a conical instrument called a top, which is placed between the strands at the point of meeting, and serves to keep them in place by laying them in the grooves on its surface, as well as to regulate the hardness of the lay. Its progress, caused by the pressure of the strands in laying, is retarded by means of stoppers or tails, which are passed around the rope between the top and upper layer.

The estimated loss in the strength of the fibre in spinning, twisting, and laying is 25 per cent., while 33 per cent. of the length is lost in the same operation.

Ropes of the smaller sizes are also made by the use of the "Woodward laying machine," which both twists the strands and lays the rope.

Small-stuff, such as marline, houseline, spun-yarn, etc., is generally made from American hemp by the process of hand-spinning.

The manufacture of rope from abaca, or manilla, differs only in the preparation of the fibre before it is spun. Rotting is not required as in the preparation of hemp fibre, but the leaf-stalks having been torn into strips, the fibre is separated from the pulp. The coarser qualities of the fibre, which are best fitted for rope, are taken from the outside layer of the stalk.

Before passing through the spreader the manilla fibre is oiled, but no tar is used except in the making of large cables, when the outside yarns of each strand are sometimes tarred.

Hides are prepared while in a green state, by being cut into strips of regular width on a revolving table, and the strips are then formed into strands and laid into rope by the processes already described.

Wire rope is used to a great extent both on shore and on shipboard, where strength and durability are required, rather than flexibility. It is made from steel or iron wire. Plain steel wire is about 56 per cent. stronger than plain iron wire, and 65 per cent. stronger than annealed iron wire. The process of annealing renders the wire less brittle and better suited for some purposes on shipboard. Both steel and iron wire may be galvanized, and this process does not detract from its strength. Small sizes of rope made from copper wire are used for lightning-conductors.

All machinery for the manufacture of wire rope is of the same general construction, but the machines are lighter or heavier, according to the size of the rope required. They consist of two parallel iron rings several feet apart, through the centres of which passes an upright shaft, connected at their peripheries by several movable iron frames, which hold the wire bobbins, the whole resembling a frame-work of cylindrical shape placed in an upright position. The bobbin-frames are connected with the central shaft by gearing in such a manner that while the cylinder revolves about the shaft, carrying the bobbins with it, a reverse motion is given to the bobbin-frames, which prevents the twisting and consequent injury to the wire. The wires meet above the cylinder, and form the strand by being twisted about a heart of small hemp line, which passes over a pulley down to the reel upon which it is wound. The process of laying the rope is the same as that of forming the strand.

The following rules for finding the breaking strain of rope manufactured at the navy-yard, Boston, has been furnished by Mr M. H. Webber, superintendent of the rope-walk:

Untarred hemp rope, square of circumference in inches × 1371.4 = strength in pounds.
Tarred hemp rope, square of circumference in inches × 1044.9 = strength in pounds.
Manilla hemp rope, square of circumference in inches × 783.7 = strength in pounds.
Steel wire rope, weight in pounds per fathom × 7098 = strength in pounds.
Charcoal wire rope, weight in pounds per fathom × 4480 = strength in pounds.

—*E. T Strong, Lieutenant U.S.N.*

Rope-walk. A long building or room where rope is manufactured. It is so called from the walking back and forth of the workmen in the operation of hand-spinning.

It is distinguished from manufactories called "cordage works," in which a different kind of machinery is used, and which do not require buildings of great length.

Connected with the rope-walk are rooms or buildings where the fibre in bales is received and hackled, where the fibre is made into ropings, and where the ropings are spun into yarns. There are also rooms for oiling, tarring, hand-spinning, etc.

Upon the floor of the rope-walk are placed the tracks for the machines used in twisting the strands and laying the rope. String-posts are placed at intervals near the tracks, from each of which a wooden arm extends several feet in length, and upon which the strands are placed after being completed. The strands are kept in

place by means of wooden pegs inserted in the upper surface of the arms.—*E. T. Strong, Lieutenant U.S.N.*

Rope's-end. The end of a rope. *To rope's-end*, to administer a drubbing with the end of a rope.

Rorqual, or Furrowed Whale. A name of Scandinavian origin applied to the finback whales, distinguished from the right-whales by the small size of their heads, shortness of their whalebone, the presence of a dorsal fin, and of a series of conspicuous longitudinal folds or furrows in the skin of the throat and chest.

Rose. An attachment to a pipe, spout, or hose-nozzle, by which a stream of water is scattered into drops or spray by passing through a perforated plate or cap.

Rose-lashing, or Rose-seizing. A lashing or seizing in which the parts are passed alternately over and under, the end being expended around the crossing.

Rosina. A Tuscan gold coin, value about $4.10.

Ross, Sir James Clark, was born in London in 1800. He entered the navy in 1812, and served under his uncle (Sir John) in the Baltic, the White Sea, the coast of Scotland, and in all the expeditions for the discovery of the northwest passage. It was while on his second Arctic voyage that he discovered, in 1831, the north magnetic pole, and on his return he was rewarded with a post-captaincy. In 1836 he crossed the Atlantic to relieve the frozen whalers in Baffin's Bay, and in 1839 he was placed in command of the Antarctic Expedition, and approached within 160 miles of the south magnetic pole. In 1843 he received the honor of knighthood. In 1848 he made a voyage to Baffin's Bay in search of Sir John Franklin, but without success. He received a number of medals, and was made a D.C.L. of Oxford. He died in 1862.

Ross, Sir John, C.B., was born June 24, 1777, at Balsarrock, Wigtonshire. He entered the navy in 1787; was promoted to lieutenant in 1802, commander in 1809, and post-captain in 1818. While a lieutenant he was wounded in cutting out a Spanish vessel from under the batteries of Bilboa, in 1806. His more important services were rendered in the Arctic regions in 1818, with Sir W. G. Parry. In May, 1829, he was employed on a fresh expedition fitted out by Sir Felix Booth, and on this expedition he discovered the peninsula of Boothia Felix, and upon his return he received the honor of knighthood, and was made C.B. In 1838 he was appointed British consul at Stockholm, where he remained some years. He became a rear-admiral in 1851, and died August 30, 1856.

Rostock, a city of Germany, in Mecklenburg-Schwerin, on the Warnow, 9 miles from its mouth in the Baltic, in lat. 54° 5′ N., lon. 10° 14′ E. It has numerous manufactories of woolen cloth, soap, and chiccory, extensive breweries, distilleries, and sugar-refineries. Its trade is extensive; the exports consist principally of superior red wheat, barley, pease, rape-seed, oats, wool, horses, cattle, and provisions, and the imports are colonial produce, wines, and manufactured goods. Vessels drawing more than 9 feet of water unload at Warnemünde, its outport. Pop. 35,000.

Rostral-crown. The naval crown anciently awarded to the individual who first boarded an enemy's ship.

Rostrum. The prow of a galley.

Rotary Blower, or Fan. A machine in which a current or blast of air is induced by the motion of vanes, blades, or fans inclosed in a suitable case provided with supply and discharge openings, and secured by radial arms to a revolving shaft so as to present their broadsides in the direction of their motion. In the ordinary fan-blower, the action depends upon the centrifugal force of the air induced by rapid revolution; and in some devices, the vanes or plates act as pistons passing round a segment of an annular space between two cylinders.

Rotary Pump. A pump by which water is thrown by the action of a rectangular piston rotating round a cylinder on an axis parallel to one of its sides and to the axis of the cylinder, though not coincident therewith. There are numerous varieties.

Centrifugal pumps, by which water is thrown by the centrifugal action of rapidly revolving *vanes*, are sometimes called *rotary pumps.*

Rotary Steam-engine. A steam-engine in which the steam acts upon a rectangular piston rotating round a cylinder on an axis parallel to one of its sides and to the axis of the cylinder, though not coincident therewith. This form of engine, of which there are many varieties, is not in general use, owing principally to the impracticability of making the piston and valves steam-tight.

Rotary Valve. A valve which, in rotating about its axis, alternately opens and closes passages or parts for the admission or ejection of steam or other fluid to or from a cylinder or other vessel.

Rotten Row. A row of old vessels in ordinary.

Rotterdam, in South Holland, in the Netherlands, is situated at the confluence of the Rotte with the Maas, in lat. 51° 55′ 3″ N., lon. 4° 29′ 5″ E. This city is more favorably situated for trade than Amsterdam; its canals admit the largest vessels. Its commerce has increased rapidly, and it now exports to the West Indies provisions, wines, and manufactured goods; to England and Scotland cheese, butter, flax, fruits, sheep, and cattle, and it has also a considerable trade with America, France, Spain, Portugal, and the northern countries of Europe. Besides its extensive commerce it has many distilleries, breweries, dye-works, refineries, and ship-building yards. Pop. 125,000.

Rouen, the capital of the department of Seine-Inférieure, France, is located on the right bank of the Seine, in lat. 49° 26′ N., lon. 1° 6′ E. The staple manufactures are cottons in a great variety of forms. It is also famous for its confectionery. There are also tanneries, sugar-refineries, copper- and iron-foundries, forges and rolling-mills. Situated as it is on a navigable river, accessible by large vessels, it has a considerable trade in grain, flour, wine, brandy, salt, oil, wool, and the various articles of its manufacture. Pop. 105,000.

Rough-knots, or Rough Nauts. Unsophisticated seamen.

Rough Log. The book in which the journal of the ship is originally written. A smooth copy,

signed by the watch-officers, is inspected by the commanding officer, and forwarded to the Navy Department. See Log-book.

Rough-spars. Cut timber before being worked into masts, etc.

Round. The rung or step of a Jacob's ladder. *A round of ammunition*, a charge for each fire-arm or piece of ordnance. *To round a point*, to sail round it; to double it. *To round to*, to haul by the wind when sailing large. *To round in*, to haul in on a weather brace. *To round up*, to haul in on a fall so as to bring the two blocks together, the movable block being disconnected from the weight. *To round down*, to overhaul a tackle to permit the lower block to descend.

Round and Grape. A term used when a gun is charged with a solid shot and grape-shot or canister. It was used in former times at close quarters.

Round Dozen. A term for thirteen lashes.

Roundhouse. A name given, in large merchantmen, to a square cabin built on the after part of the quarter-deck. In men-of-war the roundhouse is the place set apart for the convenience of the officers.

Rounding. Strands wrapped around a rope to prevent chafe.

Roundly. Quickly.

Round-ribbed. A vessel of burden with very little run and a flattish bottom, the ribs sometimes almost joining the keel horizontally.

Round Robin. A paper signed with the names arranged in a circle, so that it is impossible to tell who signed it first. The object is to prevent the singling out and punishing of the first signer.

Round Seam. A seam in which the edges are sewed together without lapping.

Round Seizing. See Seizing.

Round Shot. Spherical solid shot.

Round Splice. A long splice skillfully made.

Round the Fleet. A diabolical punishment, by which a man, lashed to a frame in a boat, was towed alongside of every ship in a fleet, to receive a certain number of lashes by sentence of court-martial.

Round-top. A name which has obtained for modern tops, from the shape of the ancient ones. See Top.

Round Turn. A turn with a rope entirely around a spar or belaying-pin. *To bring up with a round turn*, to stop suddenly and effectually. See Hawse.

Rouse. To haul with great force. *Rouse and bitt!* turn out! get out of bed!

Routine of Duty in a Man-of-war. In carrying on the duties of a man-of-war a systematic routine is adopted. This varies whether at peace or in war, in port or at sea, in warm or in cold climates; whether the ship is a cruiser, a surveying-ship, a receiving-ship, a training-ship, a practice-ship, a flag-ship, or a gunnery-ship, an armored or an unarmored vessel; but the same general ideas govern the routine in all these cases. The principal written routines are for harbor- or sea-duty, and being prepared by the executive-officer and sanctioned by the captain, are promulgated to the crew, and carried out by the watch- and junior officers. Routines are also prepared for the engine-room, and the duty in the paymaster's and surgeon's department is carried on in a systematic way, although no written routines exist. Routines are arranged with reference to the quarter, month, week, day, or watch. The quarterly routine prescribes the arranging and forwarding the reports required from all officers in command or in charge of departments, and an inspection by the commander-in-chief and staff of all vessels in the fleet. Chains and anchors are carefully overhauled once a quarter, and target practice with great guns and with small-arms, at the most convenient times, is usual. The monthly routine prescribes the reports required, and on the first Sunday the crew are mustered and the "Articles of War" are read to them; on the first Monday hammocks are scrubbed, on the second, bedding, on the third, hammocks, and on the fourth, bedding. Once a month hammocks are triced up in the rigging, opened out, and bedding thoroughly aired. Every alternate Saturday it is usual to scrub wind-sails, and every alternate Wednesday, hose-reels, boat-covers, gangway-screens, etc. On the last day of the month officers of divisions inspect the clothing and outfit of each man and make requisitions for deficiencies therein, and soon after the first of the month the paymaster issues to the crew the articles required. Money in small amounts is paid to the men each month, and mess-stores issued twice in a month. The weekly routine is subject to greater variations. On Sundays only necessary cleaning is done. After quarters and inspection of the crew, divine service is read. On Mondays, Tuesdays, Wednesdays, Thursdays, and Fridays clothes are scrubbed at sea, and on Mondays, Wednesdays, and Fridays in port. Decks are scrubbed on these days; with sand on Wednesdays, only. On Saturdays, decks are thoroughly "holystoned" with sand, guns run in, all woodwork scrubbed, and the ship thoroughly cleaned inside and out. Sometimes particular parts of the uniform are scrubbed on each day, but this is not usual. With the weekly routine is connected the drill routine, prescribing the mode of carrying on the drills. On Mondays, general quarters as for action and drills thereon, and on Fridays, a fire-alarm and drills connected with it, are usual. On Tuesdays, Wednesdays, and Thursdays the various divisions of men alternate in exercises at the guns, at small-arms, with singlesticks, pistols, howitzers, or Gatlings. Once a week battalion drill is usual, and the squadron of boats also goes out.

The daily routine is carried out by watches. The men are roused by "reveille" in port, the "idlers" at sea at early daylight, and the watch at sea at 7 A.M. The "morning" watch is consumed by the scrubbing of clothes and decks, and at sea, getting sails in order, etc. Sometimes an early breakfast is given, sometimes at 8 in port, allowing three-quarters of an hour. At sea, one watch goes to breakfast at 7.30, and the other at 8. At 8 "colors" are hoisted, and in port sails are loosed to dry or light yards sent up. The forenoon watch lasts until 12. Breakfast over at 8.30, bright metal-work is cleaned, and at 9 "sick call" is beaten for the invalids to assemble in the hospital. At 9.30 the drum beats to "quarters" for inspection, and drills follow. After they are over, the mechanics and laboring-parties go to work. At sea, the navigator is sent for at 11.30, and the sun announces

to him noon and the latitude. In port, sails when loosed are often furled at 11.30, or wash-clothes sent below. Dinner comes in all cases at 12, and one hour is allowed to all in port, half an hour to each watch at sea. Sometimes, in the afternoon, a drill with sails, boats, or muskets follows, and work is resumed. At 4, 4.30, or 5, half an hour is given to supper. Afterwards evening quarters for muster comes, and at dusk hammocks are given out. Fires are put out at 8, and "tattoo" beaten at 9. There is no routine for the night watches.—*F. S. Bassett, Lieutenant U.S.N.*

Rove. A small copper ring or washer over which the end of a nail is clinched.

Rovens. A corruption of *rope-bands*. Also, the ravelings of canvas or bunting.

Rover. A pirate or freebooter. (See PIRATE.) Also, a kind of piratical galley of the Barbary States.

Roving Commission. An authority granted to an officer in command of a vessel to cruise wherever he may see fit.

Row. To propel a vessel by oars or sweeps. *To row dry*, to so manage the oars as not to splash water into the stern-sheets of the boat. *A dry row* is a punishment administered for some offense connected with boats or rowing. The offender is sent into a boat at the davits and required to go through the motions of rowing, much to his own discomfiture and to the amusement of the ship's company. *To row in the same boat*, to hold similar opinions; to indulge in similar practices.

Several styles of rowing are to be met with in different parts of the world. We give a long full stroke with a quick return, depressing the loom just sufficient to clear the water on the return; the English generally feather high, throwing the blade above the horizontal; but the most peculiar style is that known as the *Dago stroke*, in which the oarsmen take a long stroke, and then wait for the headway to cease before giving another; it is supposed, by the people who are addicted to it, to border on the majestic. The *breast-stroke* is affected in single-banked boats; the oarsmen push the loom of the oar well forward beyond their bodies,—the worst possible application of force. *Feathering* is inclining the upper edge of the blade forward, after the stroke is finished, in order that it may be released readily from the water, and also to present a small resistance to the air on the return. If the oar is not feathered the blade is apt to be swept aft and the loom jammed in the rowlock, before it can be raised clear of the water; this is termed *catching a crab*.

ROWLOCK. An aperture cut in, or a swivel crutch fitted on, the gunwale of a boat, to act as a fulcrum for an oar in rowing.

ROW-PORTS. Certain scuttles or square holes, formerly cut through the sides of the smaller vessels of war, near the surface of the water, for the purpose of rowing them along in a calm or light wind, by heavy sweeps, each worked by several men.

Rowan, S. C., Vice-Admiral U.S.N. Through the influence of the Hon. William McLean, of Ohio, the brother of that distinguished statesman and jurist, the Hon. John McLean, an appointment as midshipman in the navy was secured for young Rowan. Before entering upon this career—a career entirely congenial to his nature and tastes—he passed some time at Oxford College, Ohio, devoting his time and attention to such studies as would be most useful in preparing himself for the profession he was about to embark in. Shortly after receiving his appointment, in 1826, he was ordered to the sloop-of-war "Vincennes," attached to the Pacific Squadron, on board of which ship, and on that station, he served a full cruise. In 1831 he was attached to the schooner "Enterprise."

Promoted to a passed midshipman, April 28, 1832, he was ordered to the sloop-of-war "Vandalia," and remained two years on board that vessel in the West Indies. In 1837 he was ordered to the store-ship "Relief," and in the same year commissioned as a lieutenant. In 1840 he was engaged on coast survey duty, and in 1843 was serving on board the line-of-battle ship "Delaware," on the Brazilian Station. In 1846–48 he was the executive-officer of the sloop-of-war "Cyane," attached to the Pacific Squadron, and took an active part in the war then waging with Mexico.* As the executive of that vessel he succeeded in impressing upon the *personnel* of the ship his own individuality, and no vessel in that squadron was more conspicuous for discipline, drill, efficiency, and service. Always in readiness, she was actively and constantly engaged, and her opportune arrival at San José, Cal., saved that stubborn fighter and brave gentleman, the noble Heywood, and his gallant party from annihilation or capture. While attached to this vessel Lieut. Rowan commanded the naval battalion under Commodore Stockton in its various operations against the enemy, and at the battle of Mesa was conspicuous for cool judgment, courage, and distinguished service. The results of this battle were the occupation of Los Angeles, the capital of the country, and the surrender of California by the Mexican governor, Don Andreas Pico, to the authorities of the United States. After the occupation of Mazatlan by the naval forces, Lieut. Rowan commanded a landing-party that marched some distance into the country and made a successful night attack upon the enemy, driving them with loss from their position; he was also engaged while attached to the "Cyane" in the bombardment of Guaymas. During the years 1850–53 and 1858–61, Lieut. Rowan devoted himself to ordnance duty in acquiring a thorough knowledge of that important branch of the service, and thus preparing himself in this respect for the high command and heavy responsibilities which were so soon to devolve upon him.

In September, 1855, he was promoted to a commander, and ordered to the command of the store-ship "Relief." The breaking out of the Rebellion found him in command of the steam sloop-of-war "Pawnee." Almost without warning this terrible civil war, with all its attendant

* Upon the arrival of Commodore Sloat in Monterey, Cal., the policy of the government in the recently inaugurated war with Mexico had not been announced to that officer, and he was left to his own judgment to determine the question. Fortunately he was surrounded by officers of the stamp of Rowan and the present Medical Director Charles D. Maxwell, than whom no officers were more zealous in advocating the immediate occupation of California, and the hoisting of our flag upon its soil. To the navy alone the Republic is indebted for the acquisition of this splendid territory with all its untold wealth.

consequences, shook the land from its centre to its remotest boundaries. Commander Rowan had married, in Norfolk, Va., the daughter of Dr. Starke, an eminent citizen of that city, and there resided; it was the home of his adoption and of his affections; there were the friends of many years, the attachments of a life. Those who know the high-strung character of this people know with what an earnest purpose they entered into the strife, and how quick they sprang to action. No time was given and none required by Rowan to determine what course he would take. Abandoning home and friends and all that made life attractive, his course was at once determined, and in the cause of the Union and in defense of the flag he drew his sword with an unfaltering spirit and determined heart. Would that the high and lofty motives actuating this gentleman had entered into the souls of those who went astray after false doctrines and heresies, and so preserved them also to the navy and the service of the country to receive its highest honors! The government, knowing the lofty character and reputation of Rowan, had no misgivings as to his loyalty, and he was continued in command of the "Pawnee." In this vessel he engaged, shortly after the breaking out of hostilities, the enemy's batteries at Acquia Creek, on the Potomac. This was the first naval engagement of the war. Later, in the "Pawnee," he participated in the attack on and in the capture of the forts and garrison at Hatteras Inlet, the first important naval success of the war, in the honors of which Commander Rowan fully shared. The joint expedition of the army and navy for operations in the waters of North Carolina, to which Rowan had been ordered as second in command, and which sailed from Hampton Roads in January, 1862, was about to open a suitable field for the display and employment of the high qualities and professional attainments he possessed. The naval force, which consisted of 17 light-draft vessels, arrived at Hatteras Inlet January 13, 1862, but the army was not fully prepared for active co-operation until three weeks later. On the morning of February 5 the combined expedition proceeded toward Roanoke Island. The naval vessels, placed by Admiral Goldsborough under the immediate command of Commander Rowan, were formed in three separate columns, commanded respectively by Lieuts. Reed Werden, Alexander Murray, and H. K. Davenport. The enemy had formed an extensive obstruction of a double row of piles and sunken vessels, stretching across the sound between the batteries on Park and Wier Points, and behind this their vessels, 8 in number, were drawn up. By half-past ten on the morning of February 7 the engagement commenced. By noon the action became general, and was continued so hotly that at two o'clock the battered barracks behind the fort were burning furiously, and at half-past four the batteries, for the most part, ceased for a while to reply to the firing of the fleet,—5 of the enemy's steamers, apparently injured, retired behind the point, and the first landing of troops took place. The landing was effected in light-draft steamers and boats at Ashby's harbor, a large body of the enemy guarding the shore being soon cleared away by some shrapnel from the guns of Rowan's flag-ship. By midnight 10,000 troops had been landed, when they were joined by a battery of six howitzers from the naval force. At nine o'clock the next morning a continuous firing in the interior announced that the army was hotly engaged about midway between the landing and Park Point, and the vessels moved up to re-engage the forts. When Burnside approached the rear of the batteries the vessels ceased firing, and proceeded to clear a passage-way through the obstructions. By 4 P.M. this was accomplished, and when the vessels burst through the obstructions the American flag was unfurled over the battery on Park Point. A few minutes afterward the enemy fired the works on Red Stone Point, together with a steamer which had taken refuge under its guns, and thus ended the eventful struggle of two days, which secured complete possession of Roanoke Island. Retreating from Roanoke Island, the enemy's fleet fled up the sound and into Pasquotank River toward Elizabeth City, Commander Rowan pursuing them with a flotilla of 14 vessels, and anchoring for the night a few miles from Fort Cobb. On the morning of the 10th they were discovered drawn up behind the battery, which mounted four heavy guns, and supported by a schooner—the "Black Warrior"—moored to the opposite bank, and carrying two heavy 32-pounders. When within long range fire was opened from the battery, schooner, and steamers, but the vessels moved on silently and steadily, shot and shell falling thick and fast among them. When within three-quarters of a mile of the battery Commander Rowan gave the signal for a dash at the enemy; fire was opened with telling effect, and the vessels pushed to their utmost speed. The enemy was completely demoralized by the bold and wholly unexpected mode of attack. The "Black Warrior" was set on fire by her officers and destroyed, the fort abandoned, and the entire fleet captured or destroyed. Passing up the river, the flotilla took possession of Elizabeth City, which the enemy had attempted to fire before hastily leaving, and Lieut. Murray was dispatched with a small force to Edenton, which he quietly took possession of on the 12th, and was then sent to obstruct the Chesapeake and Albemarle Canal, a duty which he thoroughly accomplished. At the same time Commander Rowan made a reconnoissance of the Chowan River as far as Winton, where a sharp engagement took place on the 19th; the town was the following morning occupied by the troops under Col. Hawkins, who entered the place and destroyed the military stores and quarters found there. A combined expedition of the army and navy, under Gen. Burnside and Commander Rowan, left Hatteras Inlet on the morning of March 12 for an attack upon Newbern, N. C. The fleet, numbering 14 vessels, besides the transports, entered the Neuse River in the afternoon, and at nightfall anchored in three columns off Slocum's Creek, the point selected for the debarkation of the troops, about 15 miles from Newbern. Early the following morning the gunboats were deployed on either side of the mouth of the creek, and opened with grape and canister upon the landing-place, while the troops started from the transports,—the fire ceasing as soon as the first brigade had landed. At the same time six naval howitzers, under command of Lieut. R. S. McCook, were sent ashore to assist in the attack upon the enemy's works. As soon as

the troops had landed, the flag-ship "Delaware," Lieut.-Commander S. P. Quackenbush, with another vessel, proceeded on a reconnoissance up the river, when fire was opened from Fort Dixie upon them, and a spirited engagement was kept up until dark, when all the vessels anchored for the night in a position to support the troops. At daylight on the morning of the 14th, Gen. Burnside engaged the enemy in force, and Commander Rowan advanced steadily up the river with his fleet. The passage of the river was obstructed by a formidable line of piles and torpedoes, and defended by six well-constructed forts, at distances of half a mile to a mile and a half from each other, mounting some 32 heavy guns; but under pressure of the combined attacks the enemy abandoned their defenses in succession,—the navy and army contesting the honor of raising the American flag on their ramparts,—so that at noon the fleet arrived before the deserted town of Newbern. A large quantity of public stores fell into the hands of the navy and were turned over to the troops, who arrived and took possession of the town at 2 P.M. After the fall of Newbern, Lieut. Commanding Murray was dispatched with a naval column to take possession of Washington, N. C. On April 1, Commander Rowan dispatched to New York and Philadelphia 9 vessels freighted with naval stores, some of the fruits of the capture of Newbern. Fort Macon was the next object which engaged the attention of the army and navy. On the morning of April 25, Commander Samuel Lockwood, the senior officer off Beaufort, opened on the fort in conjunction with the batteries on shore, and continued the fire for some time, until he was obliged to withdraw on account of the heavy sea. Toward evening a flag of truce appeared on the fort, and the next morning the old flag reappeared over its ramparts. Entering the fort, Commander Rowan had an interview with Gen. Burnside, with whom he signed the terms of capitulation on the part of the United States. Commander Rowan, at the same time, finding that the army had failed to accomplish the object for which it was landed at Elizabeth City, and had returned without destroying the canals, determined to undertake the work with the navy. Lieut. Hurser, with 3 gunboats and 2 schooners, with the needed means and appliances, was dispatched upon this duty, and fully accomplished the object, inflicting in two days an amount of damage that it would require months to repair.

In reviewing this brilliant series of successes and victories, of paramount value to the Union cause, we cannot fail to recognize the fine skill, untiring energy, cool and tempered judgment, quick perception and dash of Rowan, which fully establish his claims to rank with the leading naval commanders of the day. No grass grew under his keel; no victory was gained until all its fruits were fully garnered. Like the waves of the sea, success followed success, and while there was work to be done he rested not, nor allowed others to rest. This was war never better illustrated. Unlike some intrusted with high commands, who failed to follow up the result of a victory, he pursued with untiring energy and determined will the demoralized foe. Quick to perceive and prompt to act, his command of the naval forces in the sounds of North Carolina resulted in the complete restoration of the authority of the government over those waters.

Commander Rowan was promoted to a captain July 16, 1862, and as a reward for these brilliant services and for his distinguished gallantry was advanced a grade and promoted to a commodore, to take rank from the same date. In 1863, Commodore Rowan was ordered to the command of the armored frigate "New Ironsides," then in Charleston harbor operating against the enemy, and probably at the time, handled and fought intelligently, the most formidable vessel afloat. While upon this duty it was the good fortune of the writer of this article, in command of a monitor, to be a daily witnes to the fine handling of this formidable vessel and the splendid work she accomplished; to be thrown into daily intercourse with her distinguished commander; to see him upon this arduous service, in fire and out of fire, always the same wise, cool, capable, self-reliant, considerate leader and officer. While the ship in the hands of the uninitiated would have proven powerless and obstinate, under his guidance she was always reliable, acting as though she possessed a soul responsive to his own, and dutifully and obediently following his will. Nothing finer nor grander than to see this noble ship as she moves to challenge and engage the formidable forts and batteries lining the harbor at Charleston. Presently, as she comes within range, forts and batteries upon all sides open upon her a furious shower of shot and shell, and no response. Grand, gloomy, and defiant, heeding nothing but the will of her master, she moves on through the storm of battle until approaching the desired position; then Rowan turns to his famous executive, "Try the range, Belknap," and the flash and report of a single gun follow. Still, like an avenging angel, the ship moves on till another shot follows, and then a broadside of 11-inch guns with blast of fire and sound of many thunders breaks the silence of the ship, and she is alive with flame and fury,—great guns topple over, the crests of the enemy's works go down like grass before the scythe of the mower, and silence again ensues, to be followed by successive broadsides, until the enemy no longer replies. So day after day and month after month, while the monitors, with their deliberate fire of the heaviest guns, attack the defenses of the enemy, and hour after hour the battle rages unabated, when the mighty man-of-war moves majestically into position and opens upon them, the enemy soon flee to their bomb-proofs for shelter, and their guns are silent. And yet so paradoxical are the conditions of naval warfare, a single shot from one of the heavy guns of the tiny monitors and the proud career of this formidable vessel would have been speedily brought to a close. In this severe, exacting, and arduous service Commodore Rowan passed many months in command of the "New Ironsides," engaged in almost daily conflict with the enemy, and upon each and every occasion increased his bravely-earned reputation. No one can appreciate but those who have shared in the dangers, trials, and privations the character of this service, with its days of toil and exposure, and its nights of unrest and battle, where exhausted nature only found repose mid the din and sound of the conflict. In the spring of 1864, the services of the "New Ironsides" being no

45

longer required before Charleston, the ship was ordered North, and Commodore Rowan was shortly after relieved of the command.

In July, 1866, he was, by selection, promoted to a rear-admiral, and ordered to the command of the Norfolk Navy-Yard, where he remained two years. During the years 1868–69 he commanded with ability the Asiatic Squadron. While absent upon this duty from the United States he was, upon the death of Farragut and the promotion of Porter, selected by Gen. Grant as the vice-admiral of the navy, in recognition of the conspicuous and valuable service he had rendered to the republic. It was the pleasant duty of the writer to be the first to announce to Vice-Admiral Rowan his promotion, on his return to the United States, and the first to salute the flag of the newly-promoted vice-admiral. Several years subsequently, Vice-Admiral Rowan was in command of the naval station at New York, and at present is employed as president of the Board of Examiners. Admiral Rowan has but one descendant, Lieut. Hamilton Rowan, of the U. S. army, now stationed at Fort McHenry, near Baltimore, a young officer of excellent promise and reputation.—*T. H. Stevens, Rear-Admiral U.S.N.*

Rowle. A light crane, formerly much used in clearing boats and holds.

Royal. The sail next above the topgallant-sail. It is the uppermost sail ordinarily carried; those sails sometimes set above the royals are known as sky-sails, moon-sails, moon-rakers, star-gazers, etc., and are comprehended under the general term *kites*. Royals are carried only in light breezes, not only because the sails are small and their masts badly supported, but because they act with a long leverage and tend to bury the ship and retard her progress. For the gear of a royal, see under proper heads.

ROYAL-MAST. See MASTS.

Royal Fish (*Eng.*). Whales, porpoises, sturgeons, etc., which, when driven on shore, become droits of admiralty.

Royal Marines (*Eng.*). See MARINE CORPS, FOREIGN.

Royal Merchant. A title of the Mediterranean traders of the 13th century, when the Venetians were masters of the sea.

Royal Mortar. An old brass mortar of 5½ inches diameter of bore, and 150 pounds weight, throwing a 24-pounder shell up to 600 yards,—convenient for advanced trenches and boat-work.

Royals (*Eng.*). A familiar appellation for the marines since the mutiny of 1797, when they were so distinguished for the loyalty and steadiness they displayed. Also called *royal jollys.*

Roynes. An archaic term for streams, currents, or other usual passages of rivers and running waters.

Rubber. A small instrument used to rub or flatten down the seams of a sail, in sail-making.

Rubble-work. A mass of masonry, formed of irregular stones and pebbles imbedded in mortar. It is used in the interior of docks, piers, and other erections, and is opposed to *ashlar-work.*

Rudd. A fresh-water European fish of the carp family; *Leuciscus erythrophthalmus;* red-eye. It is about the size and shape of the roach, with which it is often confounded, but it has the dorsal fin farther back, a stouter body, and red irides.

Rudder. That part of the helm of a vessel which is attached to the stern-post, and by whose movements the vessel is steered.

The rudder, being turned out of the line of the keel, is acted upon by the water as the vessel passes through it, and causes the vessel to turn about her centre of gravity, the bow moving in the direction in which the rudder is turned, while the stern moves in the opposite direction.

The greater the angle which the rudder makes with the plane of the keel, the more it acts as a drag and impedes the speed of the vessel. For this reason it should be turned only so much as is necessary to steer the vessel, and in this the skill of the helmsman is shown. The arc in which the rudder can turn is seldom more than 45° on each side of the plane of the keel, and even this amount is not required to turn a vessel in the shortest time. The force that the water exerts upon the rudder varies as the square of the vessel's speed, and it is by this force that the vessel is turned. The proper amount of helm angle varies in vessels of different models, and can best be ascertained by actual experiment.

Rudders are constructed of wood or iron according to the material of which the vessel is built. A wooden rudder is composed of several pieces of timber coaked and bolted together. The upper part, called the rudder-head, is of cylindrical shape, and passes through the rudder-port in the counter to a height above the deck sufficient to connect the tiller or gear by which the rudder is turned. The piece of timber of which the head is composed extends the length of the rudder and is called the main-piece. On the forward and after sides of the main-piece additional timbers are secured, forming, from the lower part of the head (called the shoulder) to the lowest part of the rudder (called the heel), a flat structure, the after edge of which is usually of a convex shape, while the forward edge is straight and in line with the stern-post of the vessel. The rudder is hung to the stern-post by the pintles, which are fixed to the forward edge and set into the gudgeons or braces on the stern-post These constitute the hinges by which the rudder is supported and upon which it turns.

The forward edge of the rudder and the after edge of the stern-post are beveled to allow the required helm angle, and upon the lower part or heel a piece is fastened, called the sole-piece, which, like the false keel, may become easily detached if the vessel takes the ground. To prevent the rudder from unshipping, a wooden block, called a wood-lock, is placed in the aperture under the upper pintle. All of the pintles and braces and the centre of the rudder-head are in the axis of motion of the rudder. The rudder is turned on the deck of the vessel by means of a horizontal bar, called the tiller, placed in a socket in the rudder-head. Greater power is obtained in large vessels by using a wheel which is connected with the tiller by means of ropes, called wheel-ropes, or by other mechanical contrivances. Wooden rudders are sheathed with copper or yellow metal to the same height that it is placed upon the bottom and sides of the vessel to which they belong.

An iron or steel rudder is of the same general shape as the wooden rudder. It consists of a frame covered on both sides with metallic

plates, which are riveted through the frame-work to each other, and is hung to the stern-post or rudder-post by pintles and gudgeons as already described

In order to give greater breadth to the rudders of screw-steamers of great length and comparatively small depth, without an increase of strain upon the rudder-head, the equipoise rudder has been devised. It is convex on both forward and after edges, and, instead of being supported by pintles and braces, it rests upon a projection from the keel called the skeg. The axis of motion passes through the centre of the rudder-head and the centre of the socket of the skeg in which the heel rests. About two-thirds of the surface of the rudder is abaft the axis of motion, and one-third forward.

The breadth of a rudder depends, in some measure, upon the comparative dimensions of the vessel, her model, etc. A short, full vessel requires a rudder of greater breadth than a long, sharp one; while a vessel of comparatively light draft of water requires a broad rudder. The proportions in which they are usually made are 1 foot in breadth to every 100 feet in length of the vessel and 1 foot additional.

A jury-rudder is made to replace one that has been injured and rendered unserviceable. It is made from such material at hand as may be best suited to the purpose,—as spare spars, plank, etc.

A vessel may be temporarily steered by a hawser veered out over the stern, and moved toward one quarter or the other, as required, by means of tackles.—*E. T. Strong*, *Lieutenant U.S.N.*

Rudder-band. An iron band placed around the head of a wooden rudder.

Rudder-braces. The composition hinges on which a rudder turns.

Rudder-case. The casing placed around the head of a rudder. It is also termed the *well.*

Rudder-chain. One of the chains by which the rudder is secured to the quarters of the ship in the event of its being unshipped by accident.

Rudder-chock. See Chock.

Rudder-coat. An outside covering made of canvas, formerly used to prevent the water coming into the rudder casing and thence into the ship; there are better plans in use nowadays.

Rudder-horn. A kind of iron crutch bolted to the back of the rudder, for attaching the rudder-chains to in case of necessity.

Rudder-irons. The pintles, gudgeons, and braces of the rudder are frequently so called, though they are usually of copper.

Rudder-pendant. A continuation of the rudder-chains in wire rope; it usually leads up to each quarter, so as to be easily reached from the quarter-deck.

Rudder-perch. A small fish with the upper part of the body brown, varied with large round spots of yellow, the belly and sides streaked with lines of white and yellow. This fish is said to follow the rudders of ships in the warm parts of the Atlantic.

Rudder-port. The round port made in the stern of the ship in which the rudder ships.

Rudder-stock. The main piece of a rudder.

Ruffle. A low vibrating sound of the drum, continuous like the roll, but not so loud; it is used in complimenting officers of rank.

Rule-staff. A lath about 4 inches in breadth, used for laying off curves in ship-building.

Rumbelow. A very favorite burden to an old sea-song, of which vestiges still remain.

Rumbo. Rope stolen from a dock-yard.

Rumbowline. Condemned rope. Inferior rope used for securing new coils.

Run. To desert. To scud. The distance sailed by a ship. The after part of the body of a ship,—it is *clean* or *full* as it is sharp or otherwise. *To let go by the run*, to let go altogether. *To run down a coast*, to sail parallel with and near to the coast. *To run down a vessel*, to run into her bows-on. *To run down a port*, to sail into the latitude of a port and then run for it on its parallel,—a method practiced in the early days of navigation, before chronometers came into general use.

Run, Correction for. In "double altitudes," the correction for the distance passed over in the interval between the taking of the observations, to reduce one altitude to what it would have been if taken at the place of the second observation.

Run-money. The money paid as a reward for apprehending a deserter or straggler. It is checked against the accounts of the person apprehended.

Running-down Clause. A special admission into policies of marine insurance, to include the risk of loss or damage in consequence of the collision of the ship insured with other vessels.

Rundle. That part of a capstan round which the messenger is wound, including the drum-head. See Whelps.

Rune. A water-course.

Rung. The round of a Jacob's ladder.

Rung-head. A name sometimes given by shipwrights to the upper end of a floor-timber; it is more properly called a *floor-head.*

Runner. A single rope rove through a movable block, having an eye or thimble in the end, to which a tackle is hooked. A ship which risks every impediment as to privateers or blockade, to get a profitable market. *Runners of foreign goods*, organized smugglers.

Running Agreement (*Eng.*). In the case of foreign-going ships making voyages averaging less than 6 months in duration, running agreements can legally be made with the crew to extend over two or more voyages.

Running-block. The movable block of a purchase.

Running-bowline. A bowline made over the standing part of the same rope.

Running-bowsprit, or Running-in Bowsprit. A bowsprit in small craft which is rigged in when the sail is taken in. It is sometimes so fitted as to be rigged in partially when the sail is reefed.

Rupee. An East Indian coin. See Money.

Russian Navy. To Peter the Great, who reigned between 1672 and 1725, belongs the honor of creating a regular navy in Russia. The country was still in a state of semi-barbarism, and Peter saw that to enable it to cope with other European nations an effective maritime force was an essential element of strength and an instrument of civilization. As there was no one in his territories of the requisite intelligence and practical knowledge of seamanship to enable him to carry out his projects, Peter overcame a

constitutional apathy to the sea and made several voyages in trading-vessels that he might acquire an insight into navigation. Acting upon the wholesome doctrine of never leaving to others that which can be accomplished by oneself, Peter remained for some time at Archangel watching the progress of ship-building. But the crude nature of the operations not satisfying him, he went to Holland, where he labored as a common artisan in the dock-yards, and compelled his suite to follow his example. "Ships, colonies, and commerce" were the great objects of his stupendous labors. By the year 1721 something like a Russian navy was established, and Peter had the satisfaction, before his death, of achieving a victory over the Swedes in his Finland operations. Some advantages were likewise gained over the Turks in the Black Sea toward the close of the eighteenth century. Not, however, until A.D. 1803 were Russian ships of war much employed, and in that year their mission was peaceful. Two vessels were equipped for a voyage round the world.

The ambitious schemes and political complications of Napoleon Bonaparte compelled Russia to give her attention to her army, and full employment was found for it on land. Some years, therefore, elapsed before the efficiency of the navy could be tested, and in that time all the operations of the department were limited to wars with the Turks. But when the Emperor Nicholas came to the throne, in succession to Alexander, a lively movement was made toward the improvement of the maritime power of Russia. The Emperor Nicholas saw, what had long been manifest to the rest of the world, that, though the Baltic and the Black Sea afforded fine scope for nautical experiments and the construction of ships of war, those seas had each but one narrow outlet to the North Sea and the Mediterranean, and that, therefore, when engaged in hostilities with any other power, they might easily be blockaded, neutralizing the best efforts of the navy. Nothing but superior force could clear the passages for Russian commerce, or for a fair fight on the enemy's ground. Accordingly, Nicholas invited men of science and skilled artisans to accept employment at the dock-yards, which were established at Cronstadt, Nicolaief, and Sebastopol. He further founded colleges for the education of naval cadets and schools for the instruction of workingmen, and raised a battalion of pilots capable of navigating the seas of the whole world. So rapid, under the emperor's auspices, was the progress of improvement and natural strength, that, by the year 1838, the Baltic force of Russia comprehended 4 three-deckers, carrying 110 guns each, 7 carrying 84 guns, 19 armed with 74 guns, making 30 heavy line-of-battle ships, and 21 frigates of different sizes, the whole fleet being manned by 30,000 good sailors. In the Black Sea and in the Caspian there were 16 heavy ships of war, besides a large number of frigates and sloops. In this condition the Russian navy continued until 1854, when the junction of England, France, and Sardinia, in espousal of the cause of Turkey, then at war with Russia, led to hostilities in the Baltic and the Black Sea, causing serious damage to the marine force of Russia. Since the termination of the war of 1856 Russia has busily recuperated her naval force, and at the beginning of 1879 it consisted of 30 armored ships and 199 other vessels, including all classes and descriptions, carrying altogether 561 guns, and having engines aggregating 188,120 horse-power. The fleet, although numerous, is not powerful. The "Peter the Great" and "Knuz Minin" are the only two vessels on the list of sea-going armored ships which are up to the modern standard. For coast defense Russia has a considerable fleet, of which the two circular vessels, the "Novgorod" and "Vice-Admiral Popoff," are the most formidable. The next in power are 10 monitors of early date, on Ericsson's plans, similar to our harbor and river monitors, drawing nearly 12 feet of water, and armored on the sides with 5-inch plates on a backing of nearly 3 feet. The two guns in the single turret are 9-inch rifles or 15-inch smoothbores of old pattern. There are, however, two other monitors of later date and somewhat greater power, built in Russia in 1868. These are the "Tcharogeika" and "Rousalka." The side-armor is 5 inches thick, and on the turrets 6 inches. They carry four 11-inch rifles in two turrets. The speed of all these monitors is given at from 6 to 8½ knots. The chief characteristic of the two circular ironclads is that they are purely and simply sea-citadels propelled by steam, and without any attempt to make them conform to the shape of an ordinary ship. The regular cruising fleet may be divided into two branches, the American-built cruisers and the Russian-built cruisers. Two of the American vessels, the "Europe" and "Asia," were built by Messrs. Wm. Cramp & Sons, who also constructed from designs prepared by the Russian Admiralty a fourth vessel, the "Zabiaca." The "Africa" was built by Messrs. John Roach & Son, but all of them were converted into war-vessels at the yard of the Messrs. Cramp, of Philadelphia. The principal advantages possessed by these cruisers are light draft of water, high speed, and considerable sail area. The Russian-built cruisers have all been built at St. Petersburg since 1875, and were all designed by Capt. Subbotin, the Russian naval architect. The navy is represented in the Council of State by the admiral-general, a prince of the blood, who is commander-in-chief of the naval force. The head of the central administration is a minister chosen from the list of vice-admirals. There are six sections or departments of control: 1st. The Chancellery, having charge of the expenditure of the budget. 2d. The Department of the Personnel. 3d. The Hydrographic Department. 4th. The Technical Committee, divided into three sections,—construction of vessels, construction of machinery, and construction of ordnance. 5th. The Supreme Naval Tribunal. 6th. The Direction of the Health Service. The *personnel* is classified as follows:

Executive-Officers: General admiral, 1; admirals, 15; vice-admirals, 36; rear-admirals, 32; captains, first class, 223; captains, second class, 89; lieutenant-captains, 317; lieutenants, 324; midshipmen, 195. Total, 1232.

Officers of Naval Artillery: Lieutenant-generals, 2; major-generals, 2; colonels, 13; lieutenant-colonels, 9; captains, 21; staff-captains, 38; lieutenants, 20; sub-lieutenants, 42; ensigns, 47; cadets, 12. Total, 206.

Engineers of Naval Constructions and Ma-

chinery: General, 1; lieutenant-generals, 3; major-generals, 4; colonels, 7; lieutenant-colonels, 4; captains, 17; staff-captains, 22; lieutenants, 81; sub-lieutenants, 33; ensigns, 17; cadets, 6. Total, 145.

Engineer Mechanicians: Major-generals, 2; colonels, 8; lieutenant-colonels, 11; captains, 49; staff-captains, 62; lieutenants, 99; sub-lieutenants, 164; ensigns, 140; cadets, 13. Total, 548.

Hydrographic Engineers: Lieutenant-generals, 2; major-generals, 18; colonels, 18; lieutenant-colonels, 32; majors, 9; captains, 43; staff-captains, 53; lieutenants, 61; sub-lieutenants, 61; ensigns, 24. Total, 321.

Medical corps of all classes, 209.

Marine Officers: Lieutenant-generals, 3; major-generals, 3; colonels, 11; lieutenant-colonels, 36; captains, 74; staff-captains, 119; lieutenants, 94; sub-lieutenants, 96; ensigns, 60; cadets, 25. Total, 521.

Total officers, 3182; seamen and marines, 38,986. Grand total, 42,168

The cost of maintaining the Russian navy, according to the official estimates of the Minister of Marine for 1879, was $19,421,276.70. There are two dock-yards for the navy at St. Petersburg. The armaments are supplied at Cronstadt, and the principal engineering establishment is at Kolpino, on the Eshorra River; there is also a government manufactory of steel, known as the Aboukoffsky Steel-Works, located at Alexandrovsky.

Rutter, or Routier. An old word for a track-chart; it was also applied to the log-book.

Ruyter, Michel Adriaanzoon Van, the justly celebrated Dutch admiral, was born at Flushing in March, 1607, and died of wounds received in battle on April 29, 1676. The word Ruyter signifies, in Dutch, a cavalier, but in this case implies no very long descent, as it is said that the name was given to his grandfather on account of some feat of daring on horseback. The whole story is doubtful. The future admiral early made himself known among his youthful playmates in Flushing for his venturous intrepidity. When a mere child he climbed, by means of the scaffold with which workmen were executing repairs, to the top of the highest steeple in his native town, and seated himself upon the pinnacle. The workmen, not knowing that he was there, took away the scaffold and ladders; but young Ruyter, undismayed, managed to kick holes in the tiles, and to make his own way safely down to the earth again.

His family was poor, and he was early apprenticed to a rope-maker; but by dint of insisting upon going to sea his indentures were canceled, and he attained his desires by being entered as a "boy" in 1618. Four years after that he had the rating of gunner, and as such did good service during the siege of Bergen-op-Zoom by the Spaniards.

Soon after he was made boatswain of a man-of-war, when, in a fight with a Spanish vessel of about equal force, he led the boarders, and was severely wounded in the head. The Spaniards had the best of it on this occasion, and carried the Dutch off prisoners. Ruyter managed soon to escape from his Spanish prison, however, and begged his way across the whole of France, reaching Flushing in a dreadful state from hunger and exposure. After his recovery from these hardships he became an officer of a merchant vessel for a time, but soon returned to the national marine, being placed in command of a vessel fitted out for the purpose of convoying merchantmen on distant voyages. Holland was then in the height of her naval power and successful commerce, which extended to every sea.

Ruyter made several voyages abroad, to Greenland, Brazil, the West Indies, and elsewhere, increasing in experience, and always paying great attention to the study of the sciences of war and navigation.

In 1641, the Portuguese having thrown off the Spanish yoke, and the Low Countries having also revolted, it was natural that the latter should send a fleet to the assistance of the former. Ruyter served in this fleet,—at first in command of a line-of-battle ship and then as rear-admiral.

Upon his return he took command of a heavily-armed merchant vessel on a venture to America. On the voyage he was attacked by a Spanish man-of-war, when Ruyter not only successfully defended himself but sunk the Spaniard. He was by this time well known, having managed to make his name respected and feared throughout maritime Europe. In 1652, after his private voyage to America, Ruyter was placed in command of a fleet, with which he engaged that of the English Admiral Askew. Ruyter undoubtedly had much the best of the action.

In 1654 he was in command of a fleet which was ordered to reconquer the Dutch possessions on the coast of Africa, which had been seized upon by the English. Upon this occasion he made a very important and successful cruise full of very interesting incident, and reflecting great credit upon the Dutch navy and upon himself. Upon his return the States-General made him vice-admiral of Holland,—the highest rank to which a seaman could then attain, as the title of admiral was inseparable from that of stadtholder of the United Provinces.

Ruyter was at this time 47 years of age, and did not fail to prove himself worthy of the high position given him. But he was, about this period, called upon to undergo great trouble, on account of his outspoken sympathy with the brothers De Witt,—patriotic men, who died victims of calumny and popular fury. Admiral De Ruyter was, after their butchery, accused by the enemies which every man of great force of character must have of complicity with the De Witts.

While he was defending his country, in command of the fleet, a dangerous mob was threatening his house and his family. The latter were rescued, not without difficulty, and placed under the special protection of the government. Ruyter himself received many anonymous threats of violence and assassination, to which he paid no attention, and, pursuing the even tenor of his duty, outlived this temporary and unmerited unpopularity.

In 1673 the Low Countries were attacked—by land and sea—by a combination of the most powerful nations of Europe, and their very existence hung in the balance. Their action in this emergency is a model for any people, for they resolved to purchase their liberty, not only by desperate fighting, but by every sacrifice of wealth and comfort. Ruyter was charged with the defense of the coast against the combined fleets of France

and England, and in doing this he fought many general and more partial actions, winning, even from his opponents, the greatest admiration for his abilities and dauntless courage.

Count d'Estrées, the French admiral, wrote to Louis XIV. that "he would give his life for Ruyter's glory." This is rather stilted talk, but serves to show how the Dutch admiral's conduct was considered by his enemies.

When peace came at last Ruyter was past middle age, and, tired of the sea and of battles, wished to spend the remainder of his life with his family. Unfortunately for his design, in 1675 the United Provinces, now at peace with Spain, and favorably disposed towards that power, were requested to send a fleet to aid them against the French in the operations about Sicily, resulting from the revolt in that island against Charles II. As soon as they determined to send a force, the Dutch government insisted that Ruyter should command it; a commission which he accepted with great reluctance. Upon reaching the Mediterranean he had to meet Duquesne, the commander of the French fleet,—a man who, like Ruyter, had risen from very modest beginnings. They had one preliminary and partial engagement, without definite result. But, on April 22, 1676, the two fleets met near Syracuse, and a desperate general engagement ensued. There was great slaughter, and Ruyter was dreadfully wounded in both legs, while, in falling, he seriously injured himself again. In spite of this he refused to be taken below, and, lying upon a mattress, continued to give orders, conducting the retreat which he was forced to make in good order. A few days afterward he died of his wounds. His remains were taken to Holland, and there given a magnificent funeral.

All historians unite in giving Ruyter the highest position, not only as regards courage and professional ability, but moral worth. The great powers of his day held him in high esteem, and, after the battle in which he received his death-wounds, the king of Spain sent for him and his posterity the title of duke, with a considerable pension to support it. It was too late to benefit Ruyter, and his sons were too proud of their father's name to change it for a foreign one, even with an exalted title. So they refused it, as Admiral De Ruyter himself would probably have done. The king of Denmark and Louis XIV. both caused Ruyter's portrait to be painted and placed among those of their own general officers; and when the king of France heard of the admiral's death he exclaimed, "He was a redoubtable enemy; but we are forced to deplore his loss, for the man was an honor to humanity." Such pretty speeches are often put into the mouth of Louis by his historiographers; but it is at least possible that he made this one, for he is known to have had a great admiration for Ruyter. The portrait of the admiral, by Jordaens, shows an immense person, with a head large in proportion,—a little sunk between the shoulders; long hair, parted in the middle and falling on each shoulder; large, well-opened eyes; a Flemish nose, somewhat *retroussée*, and with wide nostrils; a double chin, and a long, fiercely-twirled moustache.—*E. Shippen.*

Ryde. A small stream.

S.

S. An iron hook, bent to that shape; also called a *pot-hook*. In the log-book, *s* indicates *snow*.

Sabander (for *Shah-bander*). The governor of a maritime district in Syria.

Sabine. A small fish, which is sometimes preserved in oil for food.

Sabot. A disk of wood or metal fastened to the base of a spherical projectile to keep it in the proper position while loading. All spherical shell and shrapnel in the navy have sabots, fastened to them by 4 straps of tinned iron, and further secured by a seizing at the base.

Saccade. The flap of a sail in calms and light winds.

Saccoleva. A Levantine vessel with one lateen-sail. A Greek vessel of 100 tons, with a foremast raking very much forward, having a square topsail and topgallant-sail, a sprit foresail, and two small masts abaft, with lateen yards and sails.

Saccopharynx. A genus of eels which have the power of distending the thorax like a sack.

Sackett's Harbor, Jefferson County, N. Y., is pleasantly situated at the mouth of Black River, on Lake Ontario. It has a good and safe harbor, easy of access, and was formerly an important naval station, and there is now one wooden sailing-vessel (the "New Orleans") belonging to the navy on the stocks at this place. It has greatly declined in the last 20 years, although it is becoming a popular summer resort on account of its fine scenery. Madison Barracks, garrisoned by a battery of artillery, are located here.

Sacks of Coal. The *Magellanic clouds*, patches of blue in the southern sky, near the pole.

Sacramento, the capital of California, and the second city in size and importance, is situated on the Sacramento River, at the mouth of the American River, 120 miles by water from San Francisco. Lat. 38° 34′ N.; lon. 121° 26′ W. As a centre of commerce it possesses great advantages, as it is accessible at all times of the year for steamers and sailing-vessels, while both the Sacramento and its important affluent, the Feather River, are navigable for small steamers far above, into the interior of the country, and this city is therefore the entrepôt for supplying the great mining regions of the north. It has also an extensive trade with the great central valley of the State. A large number of mills and manufactories of all kinds are located here,

the machine-shops of the Central Pacific Railroad alone employing over 1000 men. Regular lines of steamers ply daily between here and San Francisco. Pop. 20,000.

Sadalmelik. The star *α Aquarii.*

Sadalsund. The star *β Aquarii.*

Saddle. A notched piece of wood, to support a spar. The bowsprit-saddle receives the heel of the jib-boom. A wooden saddle-crutch sometimes receives the weight of the spanker-boom when not in use. An angular bar of iron on the inside of the bracket of a monitor-carriage.

Safe-conduct. A passport. A privilege granted in war exempting the party receiving it from the effects of the war during the time and to the extent prescribed in the permission. It may be granted either by the sovereign authority in a state or by subordinates in command, who are invested with the power by express commission or as an incident to their official trust. The grantor is morally bound to enforce the privilege against his own subjects or forces, and to make good any damages resulting to the holder by its violation. What is known in the army as a "safe-guard" is analogous to a safe-conduct, and its violation by any person belonging to the armies of the United States in foreign ports, or in the United States during rebellion, is by the 57th of the "Articles of War" made punishable by death.

Safety-keel (*Eng.*). A form of keel designed by Oliver Lang, giving greater security.

Safety-pin. A pin used sometimes to secure the head of the capstan-bar. A pin used in a boat-lowering apparatus to prevent the accidental detachment of the boat. A pin inserted in the tube of Singer's torpedo to prevent premature explosion.

Safety-plug. A leaden plug inserted in the inner end of a navy time-fuze to guard against accidental ignition. A plug of cement or papier-maché, used in torpedoes to prevent explosion during transport. In *mechanism*, a plug inserted in the shell of a steam-boiler or other vessel containing fluid under pressure, so fitted or made of such material as to be forced out or melted when the pressure or temperature is excessive. See Fusible Plug.

Safety-valve. A valve attached to a steam-boiler, which, by automatic action, opens and permits the escape of steam when the pressure exceeds a stated amount. The valve is confined to its seat by a weight or spring adjustable to any given pressure, and is generally provided with mechanism for opening it at will by hand. In the most common form the valve is controlled by a weighted lever. A *lock safety-valve* is one so inclosed that, after having been adjusted by an inspector, it cannot be controlled by the person managing the boiler. The area of opening of the valve should be sufficient to permit all the steam that can be generated by the boiler to escape at a pressure a little above that of the atmosphere. There are many forms of safety-valves, the principal object aimed at in all being to secure certain and prompt action.

Sag. To settle down, or yield to weight or pressure. *To sag to leeward*, to shift greatly to leeward by force of wind, sea, or current.

Sagitta. See Constellation.

Sagittarius, Constellation of (*Lat.* "The Archer"). The ninth constellation of the zodiac, lying between Scorpio and Capricornus. It contains no star above the third magnitude.

Sagittarius, Sign of. The ninth division of the ecliptic, including from 240° to 270° of longitude. Owing to the precession of the equinoxes, the *constellation* Sagittarius no longer occupies the *sign* of this name, the constellation Scorpio having taken its place. The sun is in Sagittarius from about November 23 to about December 22. Symbol ♐.

Saic. A kind of ketch, with very long masts, used in the Levant. Sometimes it has but one mast, sometimes two, and a bowsprit. No top-gallant-sails are used.

Saidak. See Ursa Major.

Saigon, the capital of French Cochin China, is situated on the Saigon River, 35 miles from the China Sea, in lat. 10° 47′ N., lon. 106° 45′ E. It consists of three towns, Pingeh, on the west side of the river, the commercial town, and the native quarter. The citadel, fortified in European fashion, contains barracks, officers' quarters, and the governor's residence. The city has a navy-yard, arsenal, floating docks, with piers and basins for shipping. It has quite a foreign trade, chiefly with Siam and China. Pop. 90,000.

Sailor. A generic term, synonymous with *mariner*, used to designate all sea-faring men. Not all *sailors* are *seamen.*

Sailor's Home. An institution for the maintenance and support of aged and infirm seamen. A Sailors' Home was instituted at Quincy, Mass., in 1866. The Sailors' Home on Staten Island, in New York Bay, is an excellent institution of many years' standing, and there are other institutions of the kind on the coast and on the lakes. Government sailors are given a home at the Naval Asylum.

Sails. The canvas, cloth, or other fabric attached to the yards, gaffs, stays, etc., of a vessel, which, when extended, are acted upon by the force of the wind.

The material in general use is canvas or duck, made of cotton, hemp, or flax. The coarser and heavier qualities of canvas are used in the large sails, where great strength is required, while the light sails, which are intended for use only with moderate winds, are made of the finer qualities.

The breadths of canvas, cut at the required length, are sewed with a flat, double seam, using for the purpose flax or cotton twine, according to the material of which the canvas is composed. The edges of the sail are finished with a broad hem called the *tabling*, and to this is sewed the bolt-rope or *roping*, by which the sail is strengthened and rendered capable of withstanding the heavy strain which is required. A draft of the sail should first be made, showing the number of cloths and the dimensions of each.

When there is sufficient space, as on the floor of a sail-loft, the measurements of the half-plan of the sail may be laid down, and the cloths cut and placed in the position where they are to be sewed.

Sails should be made to set as flat as possible, to enable a vessel to sail near the wind when close-hauled, and in order that the wind may have greater effect upon them. The set of a sail depends in a great degree upon the manner of roping, for if the canvas is too slack the sail

will extend like a bag, and much of the effect of the wind will thereby be lost.

Sails may be divided into two general classes, square and fore-and-aft. The former are quadrilateral, but not necessarily rectangular. They are always fastened or *bent* to the yards, and as the yards decrease in size the higher their position above the deck, each sail is shorter on the upper edge than on the lower. The principal square-sails are called the courses, topsails, topgallant-sails, and royals. On merchant vessels a sky-sail is sometimes carried above the royal. They are also named from the mast to which they belong, as the fore-course, or foresail, the maintop-sail, the mizzen topgallant-sail, the fore-royal, etc. The upper and lower edges are called the *head* and *foot*, and the two sides are called the *leeches*. The ropes which are sewed upon these different parts are also named head-rope, foot-rope, and leech-ropes.

The sails are bent to the yards by means of rope-yarns or spun-yarn passed through eyelet-holes made in each seam at the head of the sail, and secured to a jack-stay on the yard. At each upper corner a strand is worked through two eyelet-holes, around the roping, forming loops called the *head-cringles*, through which small ropes or lashings, called *head-earings*, are passed, and by which they are secured to the yard. The lower corners are called *clews*, and in the larger sails they are fitted with *clew-irons*, to which the tacks, sheets, and clew-lines are hooked.

Reef-bands are strips of canvas sewed across the sail parallel to the head. Eyelet-holes are made through the reef-bands at every seam in which short pieces of rope, called *reef-points*, are fastened, and serve to secure the reef-band to the yard when the sail is reduced in size by reefing. The reefs are called, commencing at the head of the sail, *single* reef, *double* reef, *third* reef, and *close* reef. At each end of the reef-bands, cringles are made, inside of which composition or iron rings (called *thimbles*) are placed.

Reef-earings are used in securing these cringles to the yards when the sail is reefed.

A variety of ropes and tackles are used in handling sails, such as *halliards*, by which they are hoisted; *sheets*, by which the clews are extended to the extremities of the yard next below; *clew-lines* and *clew-jiggers*, *bunt-lines*, *bunt-jiggers*, and *leech-lines*, which are used in pulling the different parts of the sail up to the yard upon which it is bent; *bow-lines*, which steady the leeches when sailing close to the wind; *braces*, by which the yards are moved and placed in such positions that the wind may have the greatest effect upon the sails, and *reef-tackles*, which assist in reefing the sail.

Topgallant-sails are seldom made to be reefed, but they have bunt-lines and leech-lines, while royals, being still smaller, require only clew-lines with which to take in the sail.

Studding-sails are set outside of the leeches of the fore- and main-topsails, topgallant-sails, and royals, and of the foresail. They are all quadrilateral in shape except the lower studding-sail, which is sometimes triangular. They are hoisted to the end of the yards, and the lower part is extended by means of a boom secured on the yard below. They are set and taken in by the halliards, tack, sheet, and down-haul. Studding-sails are named from the masts by which they are supported, as fore-topmast studding-sail, main-topgallant studding-sail, etc. They are used only with a fair wind and in moderate weather.

Fore-and-aft sails are those which are bent to the gaffs or masts, or are hoisted upon the stays. All square-rigged vessels carry fore-and-aft sail. In a ship or bark, the sails which are bent to the gaffs at the foremast and mainmast are called *trysails* or *spencers*, and that at the mizzen-mast is called the *spanker*. The trysails are taken in by means of *brails*, by which the sails are gathered in to the gaffs and masts, the gaffs being stationary. The spanker may be fitted in the same manner, as is usual in men-of-war, or it may be set and taken in by hoisting and lowering the gaff.

All jibs and stay-sails are bent to wooden or iron rings called *hanks*, which pass freely on the stays. They are hoisted by the halliards, hauled down by the *down-hauls*, and *trimmed* or flattened by the sheets. The jibs, fore-topmast stay-sail, and fore-stay-sail are set upon the stays which support the foremast, and are called the *head sails*. They are triangular in shape, but those stay-sails which are set between the masts are usually quadrilateral, and are named from the stays upon which they belong, as main-topmast stay-sail, mizzen-topgallant stay-sail, etc.

The lower forward corner of all fore-and-aft sails is called the *tack*, and the same term is applied to the lower outer corner of a studding-sail, and the weather lower corner of a course. The edge of a stay-sail which lies along the stay is called the *luff* or *stay*. That nearest the stern is called the *leech*, and the lower edge is called the *foot*.

The lower sails of fore-and-aft rigged vessels are named from the mast upon which they are set. A gaff-topsail is nearly triangular in shape, and is set between the topmast and the gaff.

The depth of a course, or the distance from the head to the foot, is called the *drop*. The same dimension of any other square-sail is called the *hoist*, while the width or distance between the leeches is referred to the number of *cloths* or breadths of canvas which it contains.

Various improvements have been made in square-sails by which they may be handled with greater ease with a small number of men, but the only one which is in general use in merchant ships is called the "double topsail-yard rig." By dividing the topsail into two sails, each of which can be set or taken in independently of the other, the work of handling a topsail is greatly reduced, while the same sail-surface can be extended, as in a topsail with a single yard.

Boat's sails are of different descriptions, and vary with the class of boat or the purposes for which it is to be used. Pleasure-boats are rigged with fore-and-aft sails either on one or two masts. The sails are usually of large size compared with the dimensions of the boat, for the purpose of obtaining greater speed.

The different classes of boats in the navy are of a uniform rig.

Sailing launches are *sloop-rigged*, having one mast, upon which are set a jib and mainsail.

Barges and first and second cutters are rigged with two *sliding-gunter* masts, upon which are set two triangular sails, called the foresail and mainsail, and a jib.

A sliding-gunter mast consists of two sections, nearly equal in length, called the lower-mast and topmast. The latter slides upon the former, and is held in position by means of two iron rings or bands secured to the topmast near its lower end. The sail is permanently bent to the topmast, but laced to the lower mast in order that it may not prevent the topmast from being lowered quickly. The sail is set by hoisting the topmast to its place.

Third and fourth cutters have two masts carrying *sprit-sails* and a jib. The sprit-sail is so called from the *sprit* or light spar that is used to raise and keep in position the peak of the sail. The upper end of the sprit is placed in a grommet or loop at the peak, while the lower end rests in another grommet on the lower part of the mast.

Whale-boats are rigged in the same manner with the exception of the jib.

Gigs are furnished with one mast, which carries a sprit-sail, and a stay-sail which extends from the head of the mast to the stem of the boat. Dingeys have one sprit-sail.—*E. T. Strong, Lieutenant U.S.N.*

SAIL-BURTON. A long double purchase, used for hoisting sails aloft, composed of a fiddle-block, a single-block, and a leader made fast at the latter, so that the fall acts as a guy to direct the ascent of the sail.

SAIL-CLOTH. Duck or other canvas used for making sails, awnings, etc. Hemp, cotton, and linen cloth are used in the navy.

SAIL-COVER. A canvas cover placed over a sail when furled, to protect it.

SAIL-HO! A cry given by the look-out, or any one, discovering a sail at sea. Sailors jocularly use the term when they wish to give comrades warning of the vicinity of an officer.

SAIL-HOOK. A small hook with a swivel attached, to hold sail-cloth while it is being sewed.

SAILING DIRECTIONS. Books containing local information respecting various seas and coasts useful for the purposes of navigation. The chief topics are, an account of the winds, currents, tides, with directions how to take advantage of these in making certain passages; notices of dangers, such as rocks and shoals, with directions how to avoid them; descriptions of anchorages and ports, with the appearance and bearings of landmarks for making them; the particulars respecting the light-houses on the coast; memoranda of watering-places, etc.

SAILING-ICE. Loose floating ice separated by appreciable intervals.

SAILING-MASTER was the title of a warranted officer in the U. S. navy as early as 1798. In that year John Fisher was appointed on the 12th of May, and nine others during the year. In the first printed regulations for the U. S. navy, "issued by command of the President of the United States of America," January 25, 1802, among the duties assigned to the sailing-master are "to inspect the provisions and stores," "to take care of the ballast," "to give directions for stowing the hold and spirit-room, trimming the ship, and preservation of the provisions," "to take special care of the rigging," "to navigate the ship and see that the log and log-book are duly kept," etc., etc.,—all of which duties now devolve upon the navigator, or officer next in rank to the executive. In 1813 there were 162 sailing-masters in the navy, one of whom was George Farragut, the father of the late admiral. In 1839 the title was changed to *master*, at which time there were 27 in the service, 11 of whom were in service in 1813. "*Masters in the line of promotion*," taken from the seniors of the grade of passed midshipmen to fill the death vacancies in the old-time masters, were first introduced into the service in 1846. Six were appointed the first year. In 1861 there were 36 of this grade on the active and 1 on the reserved list. In 1862, on the reorganization of the navy, by promotion and otherwise, they were all merged in the grades, and the present rank of master, a commissioned officer intermediate between the lieutenants and ensigns, was created, whose duties are simply those of a watch-officer. There still linger on the retired list 4 of the old-time warranted masters not in the line of promotion.

SAILING, ORDER OF. The disposition of a fleet under sail. It was customarily in three lines, although two were sometimes used. There were three orders of sailing, and an order of convoy and of retreat.

SAILING-ORDERS. Orders to sail in the performance of some duty.

SAILINGS. The different methods of determining a ship's track, of representing it on a chart, and of solving problems connected with it. See NAVIGATION.

SAILING-TRIM. With weights and hull well disposed, a ship is in good sailing-trim, the term having reference to her fitness to perform her best sailing.

SAIL-LOFT. A loft or room in navy-yards or shore establishments where sails are cut and made.

SAIL-LOOSERS. Those men detailed to go aloft at the times indicated, to loose the sails.

SAILMAKER. The person employed in a navy-yard to superintend all cutting, fitting, and other work on sails. A warrant-officer in the navy, charged with the same duties on board ship, receiving from $700 to $1800 a year as pay.

SAILMAKERS' BENCH. A wooden bench used by sailmakers in sewing canvas.

SAILMAKERS' GANG. The gang of men working on sail, etc., either on board ship or in a navy-yard.

SAILMAKERS' MARLINE-SPIKE. A slender iron marline-spike, with a wooden handle, used on bolt-rope work by sailmakers.

SAILMAKERS' MATE. A petty officer of a man-of-war, working at sail-making under the directions of the sailmaker, and having the care of the sails and sail-rooms. His pay is $26.50 per month.

SAILMAKERS' PRICKER. A small iron awl, used by sailmakers to punch holes in canvas; also called a stabber.

SAILMAKERS' SPLICE. A neat tapering splice, used by sailmakers in uniting two ropes of different sizes.

SAIL-MAKING. The art of cutting, sewing, and fitting sails, awnings, and other canvas structures or appendages to a ship.

SAIL-NEEDLES. Large steel needles used in sewing canvas, half their length round in section, the other half pyramidal. There are several kinds, increasing in size and strength as follows: 1, flat-seam needles; 2, tabling needles;

3, large sail needles; 4, repair needles; 5, head-rope needles; 6, small bolt-rope needles; 7, medium bolt-rope needles; 8, large bolt-rope needles; 9, small marline needles; 10, large marline needles.

SAIL-NETTING. A rope netting or a canvas receptacle for a stay-sail, as the fore-topmast stay-sail netting, etc.

SAIL-ROOM. A room below the berth-deck of a man-of-war, where sails and other canvas structures are kept. There are more than one on large ships.

SAIL-TACKLE. See SAIL-BURTON.

SAIL-TRIMMER. One of each gun's crew, detailed to go on deck to trim sails during action upon call.

SAIL-TWINE. Twine used in sewing sails and canvas in general. Two sizes are used, five-fold and four-fold, according to the texture of the canvas.

Saint Cuthbert's Duck. The eider-duck, or *Anas mollissima.*

Saint Helier's is situated on the east side of St. Aubin's Bay, on the south coast of the Isle of Jersey, of which it is the capital. Lat. 49° 11′ 3″ N.; lon. 2° 6′ W. It is located between two rocky heights, on the eastern one of which is the citadel, Fort Regent, overlooking the inner harbor. The town is the residence of many retired officers of the British army and navy. It has an active trade, and is the seat of the representative parliament of Jersey. Pop. 31,000.

Saint John, the commercial metropolis of New Brunswick, is beautifully situated at the mouth of the St. John River, on a rocky peninsula projecting into the harbor. Lat. 45° 14′ 6′ N.; lon. 66° 3′ 30″ W. The harbor is safe, capacious, and never obstructed by ice. The entrance is protected by Partridge's Island, on which are situated a quarantine hospital and light-house. On the east side of the channel a breakwater moderates the force of the waves, caused by southerly gales. This city is the entrepôt for a wide extent of country, and its situation on a large river with a good harbor, with railways running from it in all directions, and having extensive maritime and manufacturing interests, indicates its great commercial importance. It also has large interests in the fisheries. Pop. 29,000.

Saint John's, the capital of Newfoundland, is situated near the extremity of the easternmost peninsula of the island, in lat. 47° 33′ 6″ N., lon. 52° 3′ W. The harbor, an exceedingly good one, is inclosed by two mountains, between the eastern points of which the entrance called the "Narrows" is located. This entrance is well defended by fortifications. It has 12 fathoms of water, but only one vessel can pass at a time. In the harbor proper there is ample room for shipping, with good anchorage. Pop. 23,000.

Saint Malo, in the department of Ille-et-Vilaine, France, is situated on the English Channel, at the mouth of the river Rance. The town is built upon a peninsula, connected by a causeway with the mainland, and is defended by strong bastioned walls and a castle. Among the chief buildings are the chamber of commerce, naval arsenal, and school of navigation. The harbor is secure and commodious, dry at low-water, but 40 feet deep in spring tides. There is also a large floating dock. It has extensive rope-walks, manufactures of fishing-nets and hooks, and marine fittings, an active provision trade with the colonies, a brisk coasting trade, and many vessels engaged in the fisheries. Pop. 11,000.

Saint Paul de Loanda, the capital of the Portuguese province of Angola, in West Africa, in lat. 8° 48′ 1″ S., lon. 13° 13′ E., is situated on a large and secure harbor, sheltered by the island of Loanda, and defended to the seaward by three forts. Its market is well supplied, and it has an export trade in ivory, hides, coffee, and palm oil. It was once the seat of an extensive slave-trade. Pop. 20,000.

Saint Petersburg, the modern capital of the Russian Empire, is situated on both sides of the Neva, at its entrance into the Gulf of Finland, in lat. 59° 56′ N., lon. 30° 18′ E. The city is chiefly located on the south bank of the Neva, and partly on islands in the river. Owing to the flat, marshy soil upon which it is situated the city is badly drained, and is also subject to destructive inundations, during one of which, in 1824, 15,000 lives were lost. The river is open to navigation about 220 days in the year, it being frozen over the remainder of the time. The city contains many scientific schools and academies, an imperial library containing 450,000 volumes, an astronomical and meteorological observatory, naval hospital, school of mines, the imperial academy, and imperial geographical society. Manufactures of all kinds are carried on, and it has imperial gunpowder, tapestry, and porcelain factories, extensive cannon-foundries, and glass-works. It has steam-packet communication with all the principal ports of Europe. The channel at the mouth of the river is impeded by sand and difficult of access, the ship-canal to deep water being not yet completed. It has two dock-yards, and many of the vessels of the Russian navy are built here. Pop. 670,000.

Saint Sebastian, situated on a small peninsula in the Bay of Biscay, in the province of Guipuzcoa, Spain, is a fortified city, inclosed by walls, and defended by the citadel of Mota, on the adjacent height, Mount Urgull. Its harbor, protected by a mole, is small, but the city has a large import trade, and an export trade in corn, etc. Lat. 43° 19′ 2″ N.; lon. 2° 0′ 5″ W. Pop. 10,000.

Saint Servan, France, is in the department of Ille-et-Vilaine, on the right bank of the Rance, at its mouth in the English Channel. It has two harbors, one for frigates and the other for commerce, separated from each other by the rock and castle of Solidor, besides which another fort defends Saint-Servan. It has ship-building docks and an active trade. Pop. 10,000.

Saint Swithin's Day. An old superstition was, that if it rained on this day, the 6th of July, it would rain every day during the next forty.

Saker. An old gun, called in European languages *sacre*, 8 to 9 feet long, and 5 to 12 pounds calibre.

Salamander. A heated iron, formerly used in firing guns, especially in saluting. A lacing of rawhide to confine the luff of a sail to its stay.

Salem, Mass., in the county of Essex, is pleasantly situated on a peninsula formed by two inlets of the sea, called North and South Rivers. It has a good harbor, defended by Fort Pickering. The town had formerly an extensive trade with India, China, Africa, and South America;

but at present the foreign trade is small, although the coasting trade is extensive, the reception of coal for distribution and the shipment of ice being the leading interest. Quite a number of manufactories, principally cotton goods, boots, and cordage, are located here. Pop. 26,000.

Sale of Effects. When a sailor dies or deserts, his effects are sold by auction to the highest bidder.

Salerno, a city and seaport of Italy, capital of the province of Salerno, is situated at the northern extremity of the gulf of the same name, in lat. 40° 40′ N., lon. 14° 46′ E. The port is well sheltered, but is very shallow. Pop. 28,000.

Salinas, or **Salines.** Natural or artificial ponds for salt-making purposes.

Salinometer. A salt-gauge, used to ascertain the density of sea-water in the boilers, acting by specific gravity. A receptacle for holding it and the hot water is called the *salinometer-pot*, and is sometimes affixed to the boiler-front.

Sally. To make a sudden rush in a body from one part of the ship to another. It becomes useful when a ship is aground forward or aft. A *sally* would also be made to clear a certain part of the deck of boarders lodged there.

SALLY-PORT. A large port on either quarter of a fire-ship, serving as a means of escape to the crew after the train is fired. The entering or gangway port of a three-decker, or of a large modern ironclad.

Salmagundi. A sea-dish, made of slices of dried fish mixed with onions.

Salmon. A fish of a yellowish-red color, of the genus *Salmo;* it is found in all the northern climates of America, Europe, and Asia. It ascends the river for spawning in spring, and penetrates to their head-streams. It is a remarkably strong fish, and will even leap over considerable falls which lie in the way of its progress. It has been known to grow to the weight of 75 pounds; more frequently it is from 15 to 25 pounds. It furnishes a delicious dish for the table, and is an article of commerce.

SALMONET. A salmon of small size; a samlet.

SALMON-LADDER. A short trough placed in a water-fall, with passages cut for fish to pass through.

SALMONOID. Belonging to the family of which the salmon is the type.

SALMON-PEEL. A young salmon.

SALMON-TROUT. A small species of *Salmo*, resembling the common salmon in color; called also the *sea-trout*.

Salonica, in Roumelia, European Turkey, is the capital of a sanjak, at the northeast extremity of the Gulf of Salonica. Lat. 40° 38′ 8″ N.; lon. 22° 57′ 22″ E. The bazaars are extensive and well supplied, and the city has some flourishing silk-drawing factories. It is the seat of extensive trade. The exports consist of wheat, barley, maize, timber, sponges, wine, raw silk, etc. Pop. 80,000.

Saloon. The main cabin of a steamer or passenger ship. Passengers there berthed are called *saloon-passengers.*

SALOON-DECK. The deck on which the saloon of a steamer is situated.

Salt. A *salt*, or an *old salt*, is an old sailor whose life has been spent at sea.

Salt-box (*Eng.*). A case in which a temporary supply of cartridges for great guns is kept on deck.

Salt-eel. A rope's end for delinquents.

Salt-horse, or **Salt-junk.** Navy salt-beef; a part of the ration.

Salt-marsh. A marsh subject to the overflow of salt water.

Salt-water Jack. A sailor who navigates the ocean, in contradistinction to a *fresh-water Jack.*

Salute. To honor a superior by raising the cap, presenting arms, dipping colors, manning the yards, or firing a certain number of guns. In the navy, all persons salute superiors by raising the cap. All sentries salute officers below the rank of lieutenant-commander by raising the hand to the rifle at a carry; all of and above that grade, by presenting arms. The ensign is dipped in compliment to foreign men-of-war or forts, in reply to a similar salute. Boats salute according to the rank of those meeting in them, by lying on their oars, tossing, or trailing them, or by letting fly the sheets under sail, or merely by raising the cap, sitting or standing according to circumstances.

Officers on leaving or entering a ship are attended by a boatswain or his mate, and from 2 to 8 boys holding the entering ropes or standing inside the gangway. An admiral, commodore, or captain is received with a guard of marines, and drums are rolled in his honor under certain circumstances. All persons salute the quarter-deck on approaching it, by raising the cap.

Guns are fired when officers of and above the grade of commodore visit a ship, on occasions of ceremony, on national or other holidays, to foreign ships or ports, or on the visit of high civil or diplomatic functionaries. No more than 21 guns are ever fired, and they vary from that number to 5, always being of an odd number. This latter custom is very ancient, an even number being considered unlucky. Salutes are answered gun for gun, or according to the rank of the officer saluting; and the flag of the rank or of the nation saluted is hoisted when the salute is fired, and in case of personal salutes, the jib is hoisted with the first gun, and hauled down with the last. Ships carrying less than 14 guns do not salute.

Salutes. The theory of firing a salute is that it leaves the guns harmless and at the mercy of the other party, and this is so true that firing salutes with blank cartridge is a modern invention, occasioned, however, by the fact that a complimentary cannon-ball once proved fatal to the personage whom it was meant to honor. When an officer salutes he points his drawn sword to the ground, and the salute of troops is still designated "presenting arms,"—that is, presenting them to be taken.

In early times the salutes were an exchange of a few guns, as is the practice in China to-day, where the usual salute is the sensible one of 3 guns only. Edward Skippen, a traveler of the 17th century, writing in 1664, says, "One afternoon while we were at Messina, came into port two Malta gallies hung full of colors, flags, banners, etc., upon the masts, sails, etc., which made a very fair show, which gallies received pratique and then they gave 4 guns, answered by Castle Salvador with 3. Then gave the viceroy 4, who answered also with 3. At last the gallies of Sicily were saluted with 4, who returned their welcome with 3 *shot.*"

Sir William Monson, in his "Naval Tracts," written some time prior to 1600, and the earliest writer on the subject of naval salutes, says at the beginning, "I am sorry I have occasion to complain of the lavish and wasteful expense of powder in saluting ships under a friendly pretence of meeting at sea, more practised of late by our nation than any other." "A castle and the Governor of it is in the nature of a Gentleman that will entertain his Friend at his house and give him a hearty welcome, and because the castle cannot perform it in words, he makes his ordnance speak it for him with such a number of pieces as he thinks fit; after which proportion an Admiral is to answer by way of thanks, but to exceed the number of the castle's salutation, because an Admiral's ship commonly carries three times more pieces than the castle has. This is to be referred to the will of the commander on either side. If an Admiral be accompanied by his Vice-Admiral, Rear-Admiral, and the rest of his Fleet, there needs no other salutation from the castle, for the Lord-Admiral's welcome includes all the rest of his friends and fleet; but notwithstanding a Vice-Admiral must salute a castle with two pieces less than an Admiral, and the Rear-Admiral with two less than he, and this is as much to honor the Admiral as the castle; but it must be considered that these three only that carry the flags of command and rule over the squadrons, and no other ship is to shoot, unless by directions of the Admiral, for their shooting will be taken as too great a familiarity with him.

"When an Admiral shall depart from under the command of a castle, in sign of his loving acceptance for his entertainment both he and his two other flags are to give the same salutation that the castle gave him at his entrance, and with the same number of form as aforesaid.

"If a fleet pass within sight of a castle, and not within command of his ordnance to reach him, the castle is not bound to salute, only to afford a welcome and a visit by a gentleman of quality. If a Governor fail to perform any compliment that is meet, he must amend it upon the Admiral's landing, making his ordnance roar aloud his welcome; but the ship is not to answer, because it is done to the person of the Admiral, who is bound to requite the same upon the Governor's visiting him on board his ship, and his departure from thence."

It is curious to see how these regulations regarding salutes have been continued for near 300 years. Monson continues:

"The saluting of ships by one another at sea is both ancient and decent, though in this latter time much abused; for whereas 3, 5, or 7 pieces may have been the ordinary use for an Admiral, and never to exceed that proportion, and an Admiral not to answer with above one or three, now they strive to exceed that number, thinking that many pieces add honor to the salutation; but the owners of merchant ships would be gladden it might be done with less cost and more courtesy in another kind. But tho' the Admiral cannot restrain this compliment in the ship that salutes, yet he may command his gunner not to return above one or three pieces, according to the old manner.

"And for such ships as are of his own fleet he may prohibit the saluting of one another, but upon the occasions following, viz., in bringing good and fortunate news against an enemy after an escape of a desperate danger, and then not to an exceed three or five, and to be answered at the discretion of the Admiral.

"The excessive banqueting on board is a great consuming of powder, for as men's brains are heated with wine, so they heat their ordnance with ostentation and professed kindness at that instant, and many times not without danger; and therefore, to take away the cause, a captain should have directions from under the hand of a General to forbid shooting, which would be a good excuse and give his guests satisfaction, unless it be done in the manner following as I have devised.

"The vain drinking of Healths is another means to waste powder, which a General must likewise forbid, except it be the health of a free Prince, or men of that rank and condition, and then not to exceed one piece when the health shall be begun. The King's, the Queen's, or their issues, is exempted from this strictness.

"Upon some occasion an Admiral may command his whole fleet to fire their guns, as namely, when a foreign Prince, Governors of countries, Ambassadors of great Potentates, and men of Great Blood and Quality, shall be either transported, or make a visit on board the Admiral to behold the stateliness of his fleet, it were necessary they were as well resolved of their force, as the report they would make of their welcome; and in that case every ship of the Fleet is to shoot their whole number of pieces distinctly and orderly (as thus): An Admiral and his squadron first to begin; the Vice-Admiral to follow his example, and so the Rear-Admiral to do the like, but with this caution, that no small ship or pinnace do mingle themselves with great ships, but to second one another according to their Ranks and greatness.

"To come now to my proposition how things should be carried, it is thus: That upon drinking of healths, or leaves taken on board ships, instead of the excessive charge of burning powder out of great ordnance, it may be done with muskets; for a man's welcome consists not so much in the difference betwixt a cannon and a lesser piece, but in the loving heart of him who invites; both the one and the other are consumed in the twinkling of an eye, and the report of a Faulconet, when there is no greater piece, is all one to the hearer as if it were a cannon or faulcon.

"Therefore, to accommodate this difference, and to bring it to a certain custom in the King's ships hereafter, I wish that instead of the chargeable waste of powder that is now in use, by shooting out of great ordnance, to have a number of musketery placed, and decently armed and apparelled soldier-like, upon the upper deck, that when there shall be occasion to drink healths, or to take their leave at departure, they fire their muskets at a mark, made like the shape of a man, put into a barrel, off at sea within point-blank, where the soldiers shall take their aim duly. This will be an act of more pleasure and delight to the beholders than the other, where nothing is expected but the falling of a bullet having no object to shoot at; the eye, the ear, and sense, are all in action and employed together, and many other benefits arise by it; for the soldier will by this practise be made a perfect shotsman

against he shall encounter the enemy, and with so small a cost and charge that a cartridge of a cannon will entertain persons of good rank, and give them as great satisfaction with these few muskets as the number of cannon will do; for the ear is only pleased with the report a cannon makes, which lasts no longer than a flash of powder; no Gunner is made more perfect in his art, for he shoots at random in the air without level."

Not a bad idea this of the ancient marine, to combine usefulness with the observance of etiquette, which may not be amiss for modern sailors to profit by.

In 1688, Sir Cloudesley Shovel, writing from on board the "James Galley" to Sir Martin Wescomb, says, "I shall ever be carefull in keeping especially my Royal orders, which positively command me to salute neither garrison nor flagge of any forrainer, except I am certaine to receave gunne for gunne."

Salvage. An allowance made for goods saved at sea. The party saving such goods has a lien on them, and a reasonable satisfaction is made for such services. Salvage is a comparatively recent institution, unknown to the ancients, and first established by the laws of Wisby, Oleron, etc., in the 13th century. Salvage is not allowed to a government vessel. The rate of salvage varies with the danger incurred, the labor and peril of saving the goods, etc. From one-tenth to one-half the value of the property has been allowed. The crew of a ship and the passengers are entitled to no salvage for saving her. Salvage is usually provided for by insurance, and the salvage is paid by the company, except in case of high charges.

SALVAGE LOSS. The amount that the underwriters pay on property lost at sea.

SALVAGER. A wrecker who receives salvage for goods reclaimed from wrecks.

SALVOR. The claimant for salvage-money for goods saved from wreck.

Salvo. A simultaneous discharge of several pieces.

Samakeen. A Turkish coasting-trader.

Samarang, near the mouth of the Samarang River, on the north coast of Java, in lat. 6° 57′ S., lon. 110° 27′ E., is a well-built city of 60,000 population. It has a large church, military school, hospital, and an extensive trade. Its harbor is not good, and the town is unhealthy, and owes its importance to the adjacent country, which yields large quantities of coffee, pepper, rice, and tobacco. It is the residence of the Dutch governor, and the seat of one of three principal law courts of Java.

Sambucco. An Arab pinnace, used on the east coast of Africa.

Sampan. A Chinese boat, 12 to 15 feet long, with a house on it, used in the interior waters of China. All small boats are now called sampans by foreigners.

Samphire. A sea plant, antiscorbutic, the *Crithmum maritimum*.

Samshoo. A spirituous liquor, distilled in China from the yeasty fluid in which boiled rice has fermented under pressure.

Samson-post. A strong post, extending from the deck-beam to the keelson of a merchant ship, having steps cut in it, by means of which the hold is entered. A large stanchion placed diagonally on each side and against the deck-beam, its lower end being tenoned and made to ship and unship. It was formerly used to bring the fish-tackle to, when fishing the anchor; a single block was lashed near its middle to form a lead for the tackle-fall.

Sandal. A long, narrow boat of 15 to 50 tons, open, and fitted with two masts, used on the Barbary coast.

Sand-eel. A small eel-like fish (*Ammodytes tobianus* and *A. lancea*). It buries itself in the moist sand after the retiring of the tide, and is often dug out for bait and for food. *A. lancea* is the more common, and is known as the *launce*, or *sand-launce*.

Sand-flea, or Sand-hopper. A small amphipod crustacean, found on sandy shores, jumping like a flea.

San Diego, a port of entry in San Diego County, Cal., on a beautiful bay of the Pacific Ocean, 15 miles from the Mexican frontier, in lat. 32° 41′ N., has a good harbor formed by San Diego Bay. There is a depth of 22 feet of water on the bar at low-tide. Hides, whale oil, and wool are the principal articles of export, and it has quite a considerable trade. This city will probably be the terminus of the Southern Pacific Railroad.

Sand-launce. An eel-like fish, the *Ammodytes tobianus*, which buries itself in the sand.

Sand-piper. A wading-bird of the *Totanus* and *Tringa* genera.

Sand-pride. A very small species of lamprey, rarely exceeding 3 inches in length, found in the rivers of England and Scotland; called also *sand-prey*.

Sands, Benjamin F., Rear-Admiral U.S.N. Born in Maryland. Appointed midshipman from Kentucky, April 1, 1828; attached to sloop "Vandalia," Brazil Squadron, 1830–32; in sloop "St. Louis," West India Squadron, 1833–34.

Warranted as passed midshipman, June 14, 1834; on the coast survey, 1836–41.

Commissioned as lieutenant, March 16, 1840; in the frigate "Columbus," Mediterranean Squadron, 1842–44; on special duty in 1845; at Naval Observatory, 1846; Home Squadron, 1847; passage up Tabasco River, and at Tabasco, June 15, 1847; in sloop "Yorktown," and commanding brig "Porpoise," coast of Africa, 1848–50; on coast survey, 1851–55.

Commissioned as commander, September 14, 1855; continued on coast survey, 1855–58; in Bureau of Construction, 1859–60; commanding coast survey steamer "Active," 1861–62.

Commissioned as captain, July 16, 1862; commanding steam-sloop "Dacotah," North Atlantic Blockading Squadron, in 1863; in engagement at Fort Caswell, February 23, 1863; commanding steamer "Fort Jackson," North Atlantic Blockading Squadron, 1864–65,—present at both attacks upon Fort Fisher; on blockade of Wilmington, most of the time, senior officer commanding that division, from November, 1862, to February, 1865; commanding division on blockade of coast of Texas, from February to June, 1865. The surrender of the rebel trans-Mississippi forces to Gen. Canby, U.S.A., was signed by Gen. E. Kirby Smith and Major-Gen. J. Bankhead Magruder, June 2, 1865, and formal possession taken of Galveston by Capt. Sands, commanding division off coast of Texas, by hoisting our flag over the last foothold of rebellion.

Commissioned as commodore, July 25, 1866; at navy-yard, Boston, 1865–66; superintendent Naval Observatory, Washington, 1867–73.

Commissioned as rear-admiral, April 27, 1871. Retired February 11, 1874.

Sand-shot. Shot of coarser kind, cast in sand-molds.

Sands, Joshua R., Rear-Admiral U.S.N. Entered the navy as acting midshipman, September, 1812, and was at once employed under Commodore Chauncey on Lake Ontario. On the 5th of November was put under fire of the enemy in an attack of the "Royal George," which ship was compelled to retire from the fire of the American squadron to Kingston, where, protected from the batteries on shore, no further efforts were made to capture her. April, 1813, he joined sloop-of-war "Madison," and was present at the capture of Little York (now Toronto); carried orders during the greater part of the attack, from the commodore to the different vessels of the squadron, while engaged with the forts and batteries, until the enemy surrendered. May, same year, was engaged with the enemy at the capture of Fort George, Upper Canada; then served on board the sloop-of-war "Pike"; engaged several times the British squadron under Sir James Yeo; 26 men killed on board the "Pike" in one of them; served on shore in a battery on opening campaign, 1814; was ordered to join frigate "Superior," and served on board until peace was proclaimed in 1815; then ordered to the "Washington," 74 guns, bound to Mediterranean; served in her until 1818, when promoted to a lieutenant; in 1819, was ordered to sloop-of-war "Hornet," coast of Africa and West Indies; in 1821, ordered to the "Franklin," 74 guns, Commodore Stewart, employed on the Pacific until 1824; 1828, ordered to sloop-of-war "Vandalia," serving on the coast of Brazil; 1830, returned to the United States, and was variously employed on shore-duty, recruiting, etc.

1840, promoted to the rank of commander; 1841, attached to the New York Navy-Yard until 1843, then ordered to command the "Falmouth," and served in her in the years 1843–45, in the Gulf of Mexico and West Indies; 1846, was ordered to command the steamer "Vixen"; served in her in the capture of Alvarado, Tabasco, and Lagona, of which was made governor, and remained until withdrawn to take part in the attack of Vera Cruz; engaged with the castles from Point Horwas until ammunition was expended; having been supplied by the commodore, put out in front of enemy's batteries and castles in company with steamer "Spitfire" and 4 gun-boats, and remained under fire of the castle until ordered to retire by Commodore Perry; commanded the steamer "Vixen" at the capture of Tampico and Tuspan; 1847, was intrusted with the flags, trophies, and brass cannon taken from the castles, and sent home with dispatches with complimentary letter to the Department; returned to the United States in the sloop-of-war "St. Mary's," in 1848; 1848, was ordered to command the "North Carolina," and remained in her two years; 1851, ordered to command the frigate "St. Lawrence," sailed in her to World's Fair in England, subsequently visited Portugal, and returned to the United States same year; in 1853 was ordered to command the "Allegheny" for Japan,—she proved to be a failure, and was never after employed; 1856, ordered to command frigate "Susquehanna," visited Central America, Mediterranean, and England; was engaged in her laying the cable in 1857; rejoined the Mediterranean Squadron, and was again ordered to Central America, where having laid for some months in the Nicaraguan River, captured part of the filibusters and their steamer, which was left by Commodore Paulding, to whom they were sent, and then forwarded to New Orleans; while in the river, was visited with the yellow fever, and was compelled, for the want of medicines, to sail for Port Royal, Jamaica, where, after arrival, landed 83 patients, and after taking in coal, some 30 more were landed and left in the hospital; the ship now being entirely demoralized as a man-of-war, it was determined to return to the United States, and landed at New York in 1858; 1859, ordered to command the U. S. Squadron (flag-ship "Congress") on the coast of Brazil, and remained until the breaking out of the Rebellion in the United States in 1861. Retired December 21, 1861.

1862, was commissioned a commodore, and was engaged until 1866 on light-house duty on the Lakes Erie and Ontario, and St. Lawrence River, in which year was commissioned a rear-admiral; 1869, was appointed port-admiral, at Norfolk, Va., where he was stationed until 1872.

Sand-smelt. A small fish of the mullet family, and of the genus *Atherina* (*A. presbyter*).

Sand-star. A star-fish of the *Ophiura* genus, with long, slender arms.

Sand-strake. The garboard strake.

Sandusky is a port of entry and the capital of Erie County, O., and is pleasantly situated on the south shore of Sandusky Bay, in lat. 41° 27′ N., and lon. 82° 45′ W. In all seasons of the year except winter the wharves are thronged with steamboats and other vessels loading and unloading their cargoes. The harbor is a very fine one, and the city has an extensive trade. Its chief articles of export are cured fish, wool, wheat, flour, grapes, apples, and wine. Pop. 14,000.

Sand-warpt. Left on a sand-bank by the ebbing tide.

Sandwich, one of the Cinque Ports of England, County of Kent, on the south bank of the Stour, 2 miles from its mouth, in the Pegwell Bay. The town was formerly the seaport of London, but at present it has little trade, the chief exports being agricultural produce, wool, malt, bark, etc., and the principal import coal. Pop. 4000.

San Francisco, the commercial metropolis of California and most populous city on the Pacific coast, is situated on the west shore of the magnificent bay of the same name, about 6 miles from the ocean, in lat. 37° 47′ 35″ N., lon. 122° 24′ 15″ W. The city was originally built around a semicircular bay, having Rincon Point on the south and Clark's Point on the north, these two points being about a mile apart; all the space between is now filled up, the warehouses and wharves being supported by piles driven into the water. The whole business part of San Francisco is toward the city front. The most remarkable buildings are the new city hall, the custom-house, the grand opera-house, merchants' exchange, the Palace Hotel, Occidental

Hotel, Lick House, the mint, and the Bank of California. This city possesses the only large, deep, and secure harbor on the Pacific coast between Victoria and Mazatlan, except that of San Diego, and owing to this and its facilities for communication with the interior, it enjoys a monopoly of the commerce of the Pacific slope. About 50 ocean-steamers run in regular lines between this port and China, Australia, Japan, Panama, Mexico, Puget Sound, and Victoria. The harbor has an entrance 35 feet deep at low-tide, and is connected with the ocean by a strait called the Golden Gate. The chief articles of export are the precious metals, wheat, flour, wine, quicksilver, wool, barley, lumber, and hides. The total value of the yearly exports is about $75,000,000. The number of sea-going vessels that arrive each year at this port is about 4500, measuring nearly 2,000,000 tons. The city has manufactures of silk goods, cigars, furniture, boots, shoes, carriages, glass, candles, iron-castings, woolen goods, etc. At Hunter's Point, 4½ miles from the city hall, is a dry-dock hewn out of the solid rock, and said to be one of the best in the world. The entrance of the harbor is defended by Fort Point, and there is also another fort on Alcatraz Island, 2 miles north of the city. Population, according to the census of 1880, 227,350.

Sangaree. A West India punch, blood-red in color.

San Juan de Puerto Rico, the principal city and seaport of the island of Porto Rico, is situated off a small island on its north coast, in lat. 18° 29′ N., lon. 66° 7′ 2″ W. It is fortified and walled, and is one of the most healthful towns in the West Indies. The harbor is defended by forts and very safe. Pop. 27,000.

San Miguel, a harbor of the United States of Colombia, is an inlet in the Gulf of San Miguel, having an entrance 6 miles wide, and extending about 8 miles inland, with soundings in from 8 to 15 fathoms. It communicates at its inner part with Darien Harbor through two passages. Darien Harbor has a depth of from 9 to 14 fathoms at low-water, is about 16 miles long by 6 miles broad, and completely sheltered. These two harbors have been pointed out as furnishing an eligible termination to a tidal interoceanic canal between the Atlantic and Pacific.

Santa Cruz de Teneriffe is the capital of, and chief commercial port of, the Canary Islands. Lat. 28° 28′ 12″ N.; lon. 16° 14′ 48″ W. The harbor is very secure, with a capacity for 10 or 12 vessels of war. It has a mole of modern construction, which reaches far out into the sea. The coast is commanded by forts and various redoubts. Wine, brandy, almonds, and cochineal are exported. The chief industry of the place is building fishing-boats and loading and unloading vessels. Pop. 15,000.

Santander, capital of the province of Santander, Spain, in lat. 43° 28′ N., lon. 3° 41′ W., is situated on a headland on the Bay of Biscay. It has a large and secure harbor, with good anchorage and shelter, and a mole and docks, and it is the terminus of a railway to Madrid. It is a busy and thriving place, and has a cigar-manufactory, a foundry, brewery, cooperages, fish-curing establishments and tanneries, and various other industries. Pop. 31,000.

Santiago de Cuba, the second city in rank and population of the island of Cuba, on the river Santiago, 6 miles from its mouth, in lat. 19° 55′ 9″ N., and lon. 75° 50′ W., is a well-built city, with wide streets; but, being hemmed in by mountains, it is unhealthy. Its harbor, 4 miles long, is well sheltered, defended by several forts, and deep enough for large ships. In commercial importance it ranks next to Havana and Matanzas. Pop. 45,000.

Saraband. A forecastle dance, imported from African Moors.

Sardan, or **Sardel.** A sardine.

Sardine. A Mediterranean fish of the herring family (*Engraulus meletta*), about the size of the anchovy; often prepared or put up with olive oil as a delicacy. A nickname for a worthless fellow.

SARDINIÈRE. A small boat, having two lug-sails, used in the sardine-fisheries.

Sargasso Sea. From the Spanish *sargazo*, sea-weed. There are two spaces of ocean commonly known to navigators as Sargasso Seas. That in the North Atlantic, which is in places so densely covered with sea-weed as to actually impede the progress of ships, may be roughly defined as lying between the 20th and 70th meridians, and extending from 3 to 5 degrees on each side of the tropic.

The Sargasso Sea of the Pacific extends from about 140° to 175° W., and from the tropic to 40° N. Similar collections exist in the South Pacific and Southern Indian Oceans, but are of less importance to navigators, consisting principally of the giant kelp (*Macrocystis pirifera*).

The pelagic weed called gulf-weed—*Fucus natans*, or *Sargassum baccifernum*—forms the bulk of the Atlantic "Sargasso Sea," together with another variety, almost as plenty, called *Fucus vesiculosus*. These are both of a uniform brown when preserved, but when fresh their color is of a bright yellow, or chrome, contrasting beautifully with the intensely blue clear water in which they float, for they occupy the deepest portion of the Atlantic. These weeds all live attached to rocks, in certain places, as well as free, but are said *only to produce spores when attached.*

The pelagic varieties multiply by simple growth and subdivision, favored by the placid seas in which they float.

The Sargasso Sea has a fauna of its own, being inhabited by small fish of the angler family (*Antennarius*), which makes of the weed a globular nest, as large as a Dutch cheese, glued together by a gelatinous secretion of the fish itself, in which is contained the spawn. Peculiar small shrimps and crabs, and a planarian worm, swarm in the weed, as well as small turtles, membrani pores, mollusks, medusæ, and various marine insects. Besides these, small flying-fish (*Dactylopteri*) find there a secure retreat from their many enemies. All these are colored so as to blend with the colors of the weed, even to being marked with white spots, exactly resembling the older and darker pieces of the weed, which are covered with patches of membrani pores. Thus from year to year and age to age a peculiar flora and fauna are propagated in the very centres of the deepest parts of the ocean.—*E. Shippen.*

Sartori, Louis C., Commodore U.S.N. Born in New Jersey. Appointed from New Jersey, February 2, 1829; attached to ship "Warren" and schooner "Enterprise," Brazil Station, 1831–33;

frigate "Constellation," Mediterranean Squadron, 1834; frigate "Constellation," West Indies, 1835; ship "Natchez," West Indies, 1836–37.

Promoted to passed midshipman, June 14, 1837; navy-yard, Philadelphia, 1838; frigate "Constitution," Pacific Squadron, 1839–41.

Commissioned as lieutenant, September 8, 1841; receiving-ship "North Carolina," New York, 1842; receiving-ship, Philadelphia, 1843; ship "Plymouth," Mediterranean and Brazil Squadron, 1845–46; bomb-schooner "Stromboli," Mexican war, 1847–48; at the capture of Tabasco; Mediterranean Squadron, 1849–52; on board steamer "Alleghany," frigates "Constitution" and "Independence"; receiving-ship "Pennsylvania," Norfolk, 1853; Naval Asylum, Philadelphia, 1853–54; ship "John Adams," Pacific Squadron, 1855–56; commanded expedition and engagement against the Fejees, 1855; navy-yard, Philadelphia, 1857–58; commanding steamer "Water-Witch," West Indies, 1859–60.

Commissioned as commander, April 7, 1861; commanding steamer "Flag," Blockading Squadron, 1861; commanding receiving-ship "Ohio," Boston, 1862; commanding steamer "Florida," North Atlantic Squadron, 1862; commanding ship "Portsmouth," West Gulf Squadron, 1863–65; commanding steamer "Agawam," North Atlantic Squadron, 1866.

Commissioned as captain, September 26, 1866; commanding steamer "Ossipee," Pacific Squadron, 1868–69; commanding steamers "Saranac" and "Lackawanna," 1870; commanding naval rendezvous, San Francisco, 1871–72.

Commissioned as commodore, December 12, 1873. Retired June, 1874.

Sasse (*Eng.*). A fish-weir with a movable gate. A sluice or lock in a navigable river.

Satellite. A secondary planet. It is of the same nature as the primary planets about which they revolve. Nearly all the planets have one or more satellites; they are generally called *moons*, but this name is properly applied to the earth's satellite only. See MOON, PLANET.

Saturn. The planet next beyond the orbit of Jupiter; it shines with a steady, silvery light, like a star of the first magnitude, but does not twinkle. In the telescope its system of rings and satellites forms a magnificent display. There are at least two rings and eight satellites, the distance of the satellites from the primary varying from 120 thousand to 2300 thousand miles. Mean distance from sun, 905 millions of miles; length of solar day, $10^{h}\ 29^{m}$; diameter, 77,000 miles; apparent diameter, 18″; symbol ♄, representing a rude scythe.

Saucer of the Capstan. An iron saucer-shaped socket let into the step of the capstan, in which the spindle plays.

Saucer-headed Bolts. Bolts with very flat heads.

Saucisson. A powder-hose, of tarred canvas or of leather, formerly used to fire the magazine of a fire-ship.

Saugue. A small Mediterranean fishing-boat.

Saury. A fish of the genus *Scomberesox* (*S. saurus*), belonging to the pike family.

Sauve-tête. A splinter netting.

Savannah, Chatham County, Ga., is the largest and most important commercial city of the State. It is situated upon the right bank of the Savannah River, 18 miles from its mouth, in lat. 32° 5′ N., lon. 81° 8′ W. The principal buildings are the custom-house, court-house, city exchange, cotton exchange, masonic temple, and Armory Hall. The harbor is one of the best on the Southern coast, and the river is navigable for steamers to Augusta. There is on the bar a depth of water of 22 feet, and vessels drawing 19 feet can come to the wharves. Steamers run regularly to New York, Boston, Philadelphia, Baltimore, and other ports. The chief articles of export are cotton, rice, lumber, and naval stores. As a cotton port it ranks second in the United States. Pop. 36,000.

Save-all. A small sail formerly set beneath other sails to catch the wind passing under them.

Saw-bill. The goosander, *Mergus merganser.*

Saw-bones. A jocular title for the surgeon.

Saw-fish. A cartilaginous fish of the genus *Pristis*, closely allied to the sharks. It has the upper jaw prolonged into a long beak or snout, with teeth arranged along both edges. It sometimes attains the length of from 12 to 15 feet, and is one of the most formidable enemies of the whale tribe.

Sayth. A coal-fish three years old.

Scabbard. A leather or metal case for a sword or bayonet.

Scald-fish. A fish, the *Rhombus arnoglossa*, allied to the turbot.

Scaldings! A cry, used by sailors to clear the way about decks, intimating that there is danger from hot water.

Scale. A graduated bar, rod, or plate, for measuring or indicating short distances; as, a *drawing scale*, the *scale* of a thermometer, etc. A stony deposit, composed principally of salts of lime, formed on the interior surfaces of steam-boilers, in which sea-water, or water holding mineral salts in solution or suspension, is used.

SCALING-TOOLS. Tools for removing scale from the interior of steam-boilers. The principal ones are small hammers, chisel-shaped at both ends, called *scaling-hammers; chisel-bars*, which are bars of iron of assorted lengths having steel chisels wrought upon their ends; *tube-borers; scrapers;* and *rakes* or *hoes* for removing loosened scale. In addition to these, there are many devices adapted to special purposes.

Scampavia. A Neapolitan galley, or war-boat, pulling from 20 to 40 oars, with 2 lateen-sails and a jib, setting on a spit that veered abeam when the 6-pounder brass gun was fired ahead.

Scandalize. To lower a sail and haul out the reef-tackles without slacking the sheets or tying reef-points. Usually done to the mizzen-top-sail when before the wind.

Scant. Applied to a wind that heads a ship off so that she can hardly lie her course, with yards braced up sharp. *Scant timber* is that which is barely convertible to the purpose designed.

Scantling. The dimensions of a piece of timber, with regard to its breadth and thickness.

Scar. A steep cliff. Rocks bare at low-water. Gravel- or stone-beds in rivers.

Scarborough, a seaport town of England, York County, North Riding, on a headland extending into the North Sea, in lat. 54° 17′ N., lon. 0° 23′ 5′ W. It is much frequented for sea-bathing and for its mineral waters. Scarborough harbor is used as a place of shelter from the easterly

gales, is easy of access, and safe and commodious within. The bay is protected on the northeast by a high promontory. The town has a limited foreign trade, and large coastwise traffic. Pop. 25,000.

Scarbro' Warning (*Eng.*). Letting anything go by the run, without singing out.

Scarf. A joint uniting two pieces of timber. These are of various kinds, according to the location of the timbers so joined.

SCARF-BOLT. A bolt driven into a scarf; also, a bolt used for securing the false keel in wooden ships.

Scarlet-fish. A certain Chinese fish; the telescope carp. So called from its red colors.

Scat. A quick-passing shower of rain.

Scaup. The pochard, or diving-duck (*Fuligula marila*).

Schedar. The star *α Cassiopeiæ*.

Schenck, James F., Rear-Admiral U.S.N. Born in Ohio, June 11, 1807. Appointed from Ohio, March 1, 1825; sloop "Hornet," West India Squadron, 1829; frigate "Brandywine," 1830.

Promoted to passed midshipman, June 4, 1831; sloop "John Adams," Mediterranean Squadron, 1833–34.

Commissioned as lieutenant, December 22, 1835; sloop "St. Louis," West India Squadron, 1837; brig "Dolphin," Brazil Squadron, 1840; razee "Independence," Home Squadron, 1843; frigate "Congress," Pacific Squadron, 1846–47. During the war with Mexico, Lieut. Schenck, as chief military aid to Commodore Stockton, landed and took possession of Santa Barbara and San Pedro, in California; serving in same capacity, marched on and was at the first capture of Los Angeles. As second lieutenant of the frigate "Congress," was at the bombardment and capture of Guaymas and the taking of Mazatlan. Frigate "Congress," East India Squadron, 1848; commanding mail steamship "Ohio," 1848–52.

Commissioned as commander, September 14, 1855; commanding receiving-ship, New York, 1848; commanding steamer "Saginaw," East India Squadron, 1860–61. On June 30, 1861, the "Saginaw" was fired upon by a fort at "Quin Hone," Cochin China; the fire was returned and the fort silenced.

Commissioned as captain, 1861; commanding frigate "St. Lawrence," Blockading Squadron, 1862.

Commissioned as commodore, July 2, 1863; commanding steam-sloop "Powhatan," North Atlantic Squadron, 1864–65; commanded "Powhatan" and third division of Porter's squadron in the two attacks on Fort Fisher; commanded Naval Station, Mound City, Ill., 1866. Retired June 19, 1869.

Commissioned as rear-admiral, July, 1870.

School. A shoal of fish, or whales.

Schoolmaster. A petty officer in the navy, whose duty is to instruct boys.

School-ship, Nautical. A vessel commissioned under special laws for the instruction and training of boys and young men in practical seamanship and navigation.

Nautical school-ships may be established at any of the principal ports of the United States under the act of Congress of June, 1874, which allows the detail of sailing-vessels of the navy for that purpose, the vessels to be commanded and officered by naval officers, but organized and supported by the local authorities. The purpose of this act is to promote nautical education and benefit the national commerce. Such schools should be established, and as soon as possible, since ships of every class will always need skilled ready seamen, whether under sail or steam, and the duties of the seaman can be learned only by practical experience under canvas.

While gales of wind and currents are encountered at sea, the ship having the best trained and organized crew will make the best passages from port to port, and deliver her cargo in better order than vessels manned by inferior crews.

The necessary instruction to form such crews for our ships can best be given on board vessels specially intended for this service, where a system of daily drills is pursued, and where more time can be given to training boys in the duties of a seaman than would be possible in the ordinary routine of duty of a man-of-war or merchant ship making passages at sea.

The organization of a nautical school-ship should be carefully considered, as upon the character and ability of the officers and men will depend almost entirely the discipline and efficiency of the future seamen.

The duties are peculiar, and require not only high professional attainments, but also patience, good temper, and a quick appreciation of the natures and feelings of the boys who are under instruction. These qualities are absolutely essential to the commanding officer, and no one should be assigned to such duty who does not possess them in a high degree, and who is not impressed with the importance of the objects to be accomplished.

There should be a number of officers, large enough to perform all the duties of the ship at sea, and at the same time act as instructors. The graduates from the Naval Academy could be assigned to this duty with advantage, as they would be benefited in the practical exercise of professional duties while imparting to others the theoretical knowledge they obtain at that institution.

A few thorough seamen of intelligence and good character should be employed to fill the more responsible positions on board, and to act as assistants to the commissioned officers in matters of detail, squads of boys being assigned to them, and for whose conduct they should be accountable.

The discipline enforced should be firm and consistent, but as far as possible kind, and no severe punishments should be inflicted unless absolutely essential. The attention of officers and men should be directed rather to the prevention of breaches of discipline than to their detection and punishment. Uniforming the boys and putting them as far as possible in positions of trust, will be found a valuable aid in preserving the discipline on board, and should be resorted to where practicable.

The course of instruction should include not only all the duties of a seaman, from knotting and splicing to handling ship in a gale or working off a lee-shore, but also the branches of an ordinary common school course.

The length of time to be spent on board a nautical school-ship would vary, of course, with the

aptitude and intelligence of the boys themselves, and of this the instructors could best judge.

The greater portion of each year should be spent actually at sea, without regard to the seasons, as while it would not be advisable to expose mere boys to all the hardships incident to a life at sea, they should be made familiar with the management of a vessel under all circumstances, from a calm to a heavy gale.

The "St. Mary's" is now in commission as a nautical school-ship, under the management of the Board of Education at New York, and is performing highly valuable service. The "Jamestown," the vessel detailed for duty at San Francisco, was withdrawn after three years' service. No other nautical schools have yet been established.—*Henry Glass, Commander U.S.N.*

Schooner. A class of vessels first invented by Capt. Andrew Robinson, of Gloucester, Mass., in 1713. The name is derived from their swift motion through the water, the word *scoon* meaning to skip over the water. These vessels are all fore-and-aft rig, and have from two to four masts. They vary in size from 50 to more than 1000 tons. A *topsail-schooner* carries a square fore-topsail and topgallant-sail. Sometimes a schooner sets a flying square foresail in addition to her fore-and-aft sail. A *Ballahou schooner* has the foremast raking forward. *Three-masted schooners* are in common use in America, and several *four-masted schooners* are on trial. Schooners lie nearer to the wind than square-riggers, are less costly, and require fewer men to handle them, and hence are generally adopted for coasters.

Schout. A Dutch water-bailiff.

Schreight. A kind of fish.

Schultze's Powder. See EXPLOSIVES.

Schuyt. A Dutch galiot, short and round, used in the river trade.

Scitie. A small Levantine boat with three lateen-sails.

Scobs. Droppings from the blacksmith's forge.

Sconce. The head. A magazine-lantern.

Scoodyn. The furring on a vessel's foul bottom.

Scope. The length of cable by which a ship rides. This varies with the kind of bottom, nature and force of wind and tide, etc., but should never be less than three times the depth of water in which the anchor is dropped.

Score. The groove around a block in which the strap lies.

Scorpio, Constellation of (Lat. *scorpio* or *scorpius*, "The Scorpion"). The eighth constellation of the zodiac, lying between Libra and Sagittarius. The principal star, *Antares*, may be found by joining Spica with the South Balance (*α Libræ*), and continuing the line to about the same distance. *α Scorpionis* (*Cor Scorpionis*), Antares.

Scorpio, Sign of. The eighth division of the ecliptic, including from 210° to 240° of longitude. Owing to the precession of the equinoxes, the *constellation* Scorpio no longer occupies the *sign* of this name, the constellation Libra having taken its place. The sun is in Scorpio from about October 24 to about November 23. Symbol ♏.

Scorpion. A certain sea-fish. The sea-scorpion.

Scot, or Shot. A fair share or proportion. Hence, *to pay his shot* is to furnish his share of expenses.

Scotchman. A piece of wood or stiff hide placed over shrouds and other rigging, to prevent chafe by the running-gear.

Scotch Mist. Very fine, drizzling rain.

Scotch Prize. A prize that is not legal; one that should not have been made, and must be given up.

Scott, Gustavus H., Rear-Admiral U.S.N. Born in Virginia, June 13, 1812. Appointed from Virginia, August 1, 1828; frigate "Guerriere," Pacific Squadron, 1829–31; schooner "Experiment," Chesapeake Bay, 1833.

Promoted to passed midshipman, June 14, 1834; sloop "Vandalia," West India Squadron, 1835–36; waiting orders, 1837; West India Squadron, 1839–40.

Commissioned as lieutenant, February 25, 1841; frigate "Columbus," Mediterranean Squadron, 1843–44; special duty, 1845; frigate "United States," Mediterranean Squadron, 1846–47; ordnance duty, 1848–49; waiting orders, 1850; ordnance duty, 1851; frigate "St. Lawrence," Pacific Squadron, 1852–53; steamer "Michigan," on the lakes, 1855–57.

Commissioned as commander, December 27, 1856; light-house inspector, 1858–60; commanding steamer "Keystone State," special service, 1861; commanding steam-gunboat "Maratanza," North Atlantic Blockading Squadron, 1862–63.

Commissioned as captain, November 4, 1863; commanding steamer "De Soto," Blockading Squadron, 1864; commanding steam-sloop "Canandaigua," Blockading Squadron, 1865; commanding steam-sloop "Saranac," Pacific Squadron, 1866–67; member of Examining Board, Philadelphia, 1868; light-house inspector, 1869–71.

Commissioned as commodore, 1869.

Commissioned as rear-admiral, February, 1873; commanding North Atlantic Station, 1873. Retired June 13, 1874.

Scour. *To scour a beach*, to sweep it by a quick flanking fire. *To scour the seas*, to cruise piratically; to infest the seas.

Scouse. A sea-dish made of soaked and pounded biscuit and meat cut into small pieces. Where no meat is used, it is called *bread-scouse*. Where other ingredients are introduced, it is called *lob-scouse*.

Scow. A large, open, flat-bottomed boat.

Scrabble (*Eng.*). A badly-written log.

Scraler. The puffinet (*Colymbus grille*).

Scrape. The upper spars and the yard-arms of a man-of-war are kept bright, and it is customary to scrape them at least once in 3 months, or oftener. After they are scraped with knives, they are covered with *slush*.

Scraper. A triangular iron instrument with sharp edges, used in scraping parts of a ship. Scrapers are sometimes square, when they are called *tree-scrapers*, and sometimes have one point cut off, as in *deck-scrapers*. Also, a name for a cocked hat.

Scratch-race. An impromptu race, where crews volunteer or are drawn by lot.

Scrawl. The young of the *dog-crab*.

Scray. The sea-swallow, or tern (*Sterna hirundo*).

Screen. A canvas partition used about decks for various purposes. Coal-screens are used while coaling ship, to prevent the dust from

coming into the officers' quarters. Screens are used to form a room on the gun-deck for a court-martial, for school, or to separate a sick man from the crew. *Fire-* or *magazine-screens* are made of thick fearnaught.

Screw. A convex or concave cylinder with one or more helical projections, called *threads*, winding round it. The advance made in direction of the axis of the cylinder by one convolution of the thread is called the *pitch*. Convex and concave screws are designated technically by the respective names of *male* and *female*; a short concave screw fitted to a convex screw is called a *nut*, and when a screw is spoken of without qualification, a *convex* screw is usually understood. Screws intended to penetrate wood are usually pointed at the entering end.

A *compressor-screw* is used on a slide gun-carriage to increase the friction and decrease the recoil; an *elevating screw*, to depress or elevate the breech of the gun; a *thumb-screw*, to hold the sight in place. A *jack-screw* is a portable machine for raising heavy weight, acting by a screw. *Rigger's screws* are iron frames in which a screw works, moving a clamp, so that the parts of the rigging may be brought together as in a vise. A *rigging-screw* is an iron frame with a screw working in it, to the upper end of which a shroud is attached, while the frame is made fast to the channels. See SCREW-PROPELLER.

SCREW-BOLT. A bolt whose lower end is terminated by a screw. A *screw eye-bolt* is a screw terminated by an eye-bolt. A *screw ring-bolt* is a screw with a ring attached to its head.

SCREW-BOX. The box in which the foot of an elevating screw works.

SCREW-CLAMP. An iron half-frame with a screw attached to its upper portion, so as to be used as a portable vise. Used by ship-carpenters to bring two pieces of timber together.

SCREW-DOCK. An apparatus used for raising small vessels out of the water for graving purposes. It consists of a platform which has blocks and shores upon it; this platform is raised or lowered as required by the use of iron screws of large diameter, the screws being attached to a stationary frame above, as well as to the platform to be raised. The vessel is first floated and secured upon the blocks, and then raised to the desired height.

SCREW-FID. A fid for a mast, having a screw attached, by which it is withdrawn.

SCREW-GAMMONING. A gammoning consisting of a plate or chain fastened by a screw.

SCREW-PILE. A pile sunk by a screw on its lower end.

SCREW-POST. The main stern-post in a screw-steamer, through which the screw-shaft passes.

SCREW-PROPELLER. A contrivance for propelling a vessel by the action of a screw in the water, which serves as a *nut*. It consists of two or more *blades* or *vanes*, each forming a portion or helicoidal sector of a screw-thread, attached to a hub or centre revolving in a plane perpendicular to the direction of the motion of the vessel. It is made of cast iron, steel, or composition, and the blades may be either cast upon or bolted to the hub.

There are numerous varieties, differing widely one from another in the number and contour of blades, area presented to the resistance of the water, and in nature of *pitch*, which may be uniform or increasing either in direction of the axis or from hub to periphery. In the *plain true screw* the generatrix is a straight line projecting radially from the axis in a plane perpendicular thereto, one directrix being the axis and the other a helical curve of uniform pitch; but the generatrix may be curved or inclined in any direction, the angular directrix of variable pitch, or there may be two angular directrices differing one from another in pitch; and by combining these various conditions, an infinite variety of warped surfaces may be formed.

No general theory of the screw-propeller has yet been established, and engineers construct it in accordance with their personal investigations and experience, many preferring the plain true screw. It may be observed, however, in the matter of general proportions, that the pitch should be such as to permit the highest practicable velocity of engine piston; the diameter such that the screw will be so thoroughly submerged as to avoid loss of power in throwing water off in spray; the contour of the blades so designed as to reduce to a minimum the vibrations caused when they pass the stern-post; and that in some very satisfactory screws the total area projected in direction of the axis is about four-tenths of that of a circle having the same diameter. Screws that produce good results at some rates of speed are found to be less efficient at others.

This instrument is believed by some to be an early invention of the Chinese. Many claims have been made to its invention in modern times. Mr. J. Stevens, of New York, seems to have made the first attempt to apply it to the propulsion of a vessel. In 1804 he propelled a boat by some form of a screw. In 1815 the English engineer Trevethick patented a worm or screw revolving in a cylinder at the sides or stern of a vessel. In 1816, Robert Kinder applied for a patent for a shaft and screw of nearly the form now in use. The French claim the invention, and only a few years ago they erected at Boulogne a monument to Frederic Sauvage as the inventor.

The first demonstration of its value on a proper scale was made in England during the year 1836, by Capt. John Ericsson, a Swedish engineer, and now a resident of New York. After an experiment with a model he applied the screw to a boat 45 feet in length, named the "Francis B. Ogden," and made successful runs on the river Thames. Experiments were made in the presence of the Lords of the Admiralty by towing their barge 10 miles an hour; yet this same board reported the screw-propeller unsuited for vessels of war. In 1826, Mr. Woodcroft patented a screw-propeller. In 1836 or 1837, Mr. T. P. Smith took out a patent for a screw made to revolve under water in a recess at the side of the vessel, and the following year exhibited it in a small vessel. Soon after this it was applied to a vessel of 237 tons, called the "Archimedes." This vessel was tested against the "Widgeon," the fastest paddle-wheeler plying between Dover and Calais, and thus established the screw as a successful instrument of propulsion in England.

The British Admiralty at length ordered a screw-vessel, named the "Rattler," to be built from the same model and dimensions as the pad-

dle-wheel vessel "Alecto," then building. This was 8 years after Ericsson demonstrated its practicability, and after he built the screw-vessel "Robert F. Stockton," 70 feet long by 10 feet wide, at Birkenhead.

The "Rattler" proved successful, and established the necessity of adopting the screw in the British navy. (The screw used on this vessel is now in the South Kensington Patent Museum.)

Previous to the construction of the "Rattler," Capt. Ericsson came by invitation of Commodore Stockton, U.S.N., to Philadelphia, and there built the first war screw-steamship (the "Princeton") that ever cruised at sea.

This ship was launched in 1842, cruised on the coast in 1845, burst her big wrought-iron gun on the Potomac in 1843, by which accident several members of President Tyler's Cabinet were killed. She served on the blockade of the coast of Mexico in 1846–47; crossed the Atlantic in the latter-named year in search of Mexican privateers; returned home in July, 1849, and was broken up.

SCREW-PROPELLER GOVERNOR. See GOVERNOR, or MARINE GOVERNOR.

SCREW-PROPELLER WELL. A vertical pit or opening at the stern and through the counter of a vessel, into which the propeller is hoisted when sail-power alone is used.

SCREW-SHAFT. An engine shaft turning a screw-propeller.

SCREW-STEAMER. A steamer propelled by a screw.

Scrimp. Scant,—applied to the wind.

Scroll-head. A piece of timber joined to the knee of the head under the bowsprit, in place of a figure-head, which turns outward.

Scrovies. Old or worthless seamen sent on board by *crimps*.

Scrub. To scour the decks, hammocks, etc., with sand or soap. Decks are scrubbed with water only, with sand and broom, or are *holystoned* with sand.

SCRUB-BROOM. A coarse broom for scrubbing, made out of hickory strips, or coir.

SCRUB-BRUSH. A brush for scrubbing, made out of coir, or hog's bristles.

Scruff. The fur adhering to the bottoms of foul vessels.

Scud. Loose, vapory clouds, driven rapidly by the wind. *To scud*, to run before a gale with sufficient low canvas to keep the ship ahead of the sea. When a ship carries no sail, she *scuds under bare poles*. *To scud like a 'Mudian* (*Eng.*). to be off quickly.

Scull. An oar so short that one man may use a pair readily. A short oar used over the stern in propelling a boat. *To scull*, to row a boat with a pair of sculls, or to propel her by an oar over the stern, worked from side to side, and turned in the water, like a screw. Japanese boats are propelled very rapidly by means of sculls.

Sculpin. A fish of the genus *Cottin*. A fish, the *Callonymus dracunculus*.

Sculptor. See CONSTELLATION.

Sculptures. The carved decorations of the bow and stern of an old ship of war.

Scum. Refuse at change of tide. Fresh water running through salt, carrying physalia and other gelatinous animals with it in a line of foam. Thin atmospheric vapor; scud.

Scupper. A hole cut through the water-ways and the side of the ship, to carry off the water from the decks. Also called *scupper-hole*.

SCUPPER-HOSE. A canvas or leather pipe nailed over the lower end of the scupper-holes, to keep the water from staining the ship's side.

SCUPPER-LEATHER. A leather valve, nailed over a scupper-hole, so as to allow no water to enter from outside.

SCUPPER-PLUG. A wooden plug, cut to fit the scupper-hole, so as to close it when desired.

SCUPPER-SHOOTS. Tubes of metal covered with wood, to carry the water from the spar-deck to the sea.

Scurry. A sudden fright, as of birds or fish.

Scurvy. *Definition.*—A special disease of malnutrition, affecting mainly the constitution of the blood, and dependent upon deprivation of vegetable food, attended by hemorrhages, livid spots under the skin, swollen, spongy, and inflamed gums, and general debility, not necessarily accompanied by fever.

History.—Hippocrates gives a description of symptoms closely corresponding to what we now recognize as scurvy.

Celsus (lib. ii. c. vii.) speaks of the ulcerations attending scurvy in a graphic manner.

Aretæus, Paul of Ægina, and Avicenna, have noted the same chain of symptoms. Strabo and Pliny are supposed to allude to scurvy in the Roman army, and its cure by a certain herb, called *Herba Brittanica*.

The Sieur de Joinville gives a particular account of the ravages of scurvy in the French army under Louis IX. during the crusade against the Saracens of Egypt.

But the most terrible records of scorbutus are found in naval annals. More lives were sacrificed in former times by this disease than by all other causes combined, whether sickness, tempest, or battle (Wood).

Inefficiency and neglect in the allied armies' commissariat during the Crimean war caused severe suffering from scurvy; but during the late civil war in America it was not a source of any considerable mortality.

Nevertheless, some U. S. army hospitals recorded large numbers of cases where the scorbutic taint was the cause of serious and protracted disease, which was cured by its removal.

Symptoms.—Unwillingness and disability for bodily exertion, pallor, puffiness of face and limbs, livid and swollen gums, hard and painful swellings of the muscles, hemorrhages from mucous surfaces, bruised discolorations of the skin, excessive debility, and (often) extremely unhealthy ulcerations characterize the disease.

Causes.—The one essential cause of scurvy is the absence of sufficient vegetable food. It is not due—as formerly supposed—to living upon salt meat, but only to living upon it exclusively. It will not occur when vegetables are freely used, and it may break out when they are deficient, though an abundance of fresh meat be supplied.

Predisposing and assisting causes may be enumerated; *e.g.*, previous disease, unwholesome diet, bad water, foul air, or, in fact, whatever weakens the system, or tends to deprave the blood.

Treatment.—This consists in supplying the necessary food whose absence caused the disease. A sufficiency of fresh vegetables and fruits will

cause rapid and almost immediate cure of even the most desperate cases.

Most acidulous fruits, especially limes, lemons, oranges, and others of the family of *Aurantiaceæ*, are efficient remedies. To Dr. G. Perin, U.S.A., we owe the knowledge of the superior curative virtues of the juice of the *Agave Americana*, in doses of two or three fluidounces three times a day. Potatoes, cabbage, turnips, carrots, water-cresses, onions, and radishes are among the most desirable vegetables for use in this disease.

Cider, malt liquors, and wines should be allowed.

Prevention.—Absolute certainty attends preventive measures against scurvy. It is only necessary in sea-voyages to attend to cleanliness and ventilation of vessels, the general comfort of the crews, and the supply of sufficient lime-juice to distribute an ounce per diem to each man on board ship.

In armies and hospitals, the only requisite is a varied vegetable diet.

Practically, scurvy is no longer a scourge by sea or land, and can become so only by inexcusable neglect.—*John T. Carpenter, President Pennsylvania State Medical Association.*

SCURVY-GRASS. The spoon-wort, a grass of the genus *Cochlearia*, formerly eaten as a salad, to cure scurvy, or prevent it.

Scutch. To separate the fibre of hemp from the woody part by beating.

SCUTCHER. A wooden sword for breaking hemp.

Scuttle. A small opening in the deck of a vessel not over two feet square; they are generally made flush with the decks, without coamings. *To scuttle a ship*, to sink her by boring holes in her bottom.

SCUTTLE-BUTT. A cask, having a square hole cut in its bilge or head, with drinking-water in it for the men's use.

Scuttle-fish. The cuttle-fish (which see).

Sea. The swell or billowy motion of the ocean; a high wave or billow. *At sea*, away from the land; on the ocean. Figuratively, bewildered, confused. *To ship a sea*, to receive a portion of a wave over the rail of a vessel. *Half-seas o'er*, half-drunk, tipsy. *High seas*, the open sea; where the tide ebbs and flows. *Full sea*, high-tide. See CHOPPING, COCKLING, CROSS, GREEN, etc.

A sea is a body of salt water, only less in size than an ocean. The same word is used to designate lakes, as the Dead Sea and Sea of Aral, and likewise expresses the idea conveyed by the word ocean, meaning the whole mass of water. The movement of the water in waves and surges is called by the sailor a sea, the figure of speech being exactly opposite to that in the last case. Seas are only inferior to oceans in size, although there are some small seas, such as Marmora and Azof, neither exceeding 5000 square miles in extent. The seas emptying their waters into the Arctic are the White Sea, having an area of 10,000 square miles, the Kara Sea, containing 100,000 square miles, and Greenland Sea, about the same area. These seas, frozen during much of the year, are little navigated. Into the Pacific empty the following Asiatic seas: 1. Behring's Sea, containing some 145,000 square miles, washing also the coast of Alaska and the chain of Aleutian Islands. It is important for its fisheries, the seal and whale abounding. 2. Kamchatka Sea, an arm of the latter, containing some 58,000 square miles, and washing the shores of Kamchatka. Several bays open on it, and the important port of Petropaulowski is situated on one of them. 3. Sea of Okhotsk. The Kamchatka peninsula and the Kurile Islands separate this large sea, containing 180,000 square miles, from the Pacific. Many bays open into it, and Saghalien Island is situated in it. 4. The Sea of Japan, connected with the latter by two straits, and separated from the Pacific by the Japan Islands, contains 150,000 square miles. The Corea Channel connects it with (5) the Yellow Sea, opening into (6) the Eastern Sea. Both these seas wash the shores of China, and receive the waters of the mighty Hoang-Ho and Yangtze-Kiang. The former has 130,000, the latter 115,000 square miles of area. Their navigation is most important. The former gets its name from the mud brought down by the rivers, and a like cause shallows them to some extent near the coast. 7. The China Sea. This immense sea, containing 420,000 square miles, washes the shores of China, Anam, Malay peninsula, Philippine Islands, and Borneo. It connects by channels and straits with the Eastern Sea, Bengal Sea, Indian Ocean, Pacific Ocean, and the three following seas. Many important ports, as Singapore, Bangkok, Hong-Kong, Canton, Manila, and others, are situated on or near it, and its navigation is very important, and commerce extensive. Many shoals and islands exist in it. It is the fourth in size of the great seas. 8. Mindon Sea, 142,000 square miles. 9. Celebes Sea, 216,000; 10. Java Sea, 173,000; 11. Floris Sea, 72,000; 12. Banda Sea, 75,000; 13. Arafura Sea, 172,000 square miles. All these are situated in the Malaysian Islands, connecting with each other, and with the Pacific and Indian Oceans. They are the channels of communication in this island world, and are much encumbered by small islands.

The seas emptying into the Indian Ocean are, 1. Bengal Sea. This, with the gulf of the same name, lies between the Eastern provinces and the Western Indian peninsula. It contains 360,000 square miles, and is next in size to the China Sea. 2. Arabian Sea. This sea, containing 560,000 square miles, washes the shores of Arabia, Beloochistan, and India. Into it empty the Persian Gulf and the Red Sea, and the waters of the Indus, Euphrates, and Tigris find their way through it to the Indian Ocean. It was the scene of an ancient commerce, and the trade of India and China is again brought through it by the opening of the Suez Canal. 3. Red Sea. This is a long, narrow sea, between the sandy regions of Arabia and Egypt, and is hot, very salt, and difficult of navigation. But the commerce of the East finds its way through it, and its navigation is most important. The northern end is at a lower level than the southern, and its waters find their way into the Arabian Sea by the Straits of Bab-el-Mandeb and the Gulf of Aden. It connects with the Mediterranean by the Suez Canal. No seas open into the Pacific from the west coast of America. On its eastern shores is but one, the Caribbean Sea, the largest in the world, containing 705,000 square miles. It washes the shores of South America, Central America, and the West India Islands, which

latter separate it from the Atlantic. It connects with the Gulf of Mexico by Yucatan Channel, and contains Jamaica and many smaller islands. Its navigation, rendered more important by a railroad, will be far more increased by the completion of a projected canal, but its many islands and shoals, and its numerous storms and calms, are serious impediments.

The seas opening into the Atlantic from the shores of Europe are many and important. To the north are the Irish Sea, measuring 8000 square miles; the North Sea, 172,000; and the Baltic, 155,000. The North Sea washes the coasts of the British Isles, Holland, Denmark, Belgium, and Norway, and through it passes the large and important commerce of the North. Into it opens the Zuyder Zee, a shallow sea in the north of Holland, and through it the Baltic empties its waters into the Atlantic by the Cattegat and Skager-Rack Sounds. The Baltic, with its arms, the Gulfs of Bothnia and Finland, penetrates far into the European continent, washing the coasts of Germany, Sweden, and Russia. Its entrance is exceedingly difficult, and it contains many large islands and innumerable small ones near the coast, making its navigation difficult. Its shores are everywhere flat, and many gulfs and 240 rivers—many of them large—empty into it. Its water is very fresh, and it is quite shallow in places.

The Mediterranean, with its chain of seas, is the only other sea opening into the Atlantic. It is only inferior to the Caribbean in size, having an area of 690,000 square miles. It lies between Europe, Asia, and Africa, and has for centuries been the scene of the most important commerce. Into it open the following seas: 1. Tyrrhenian; 2. Ionian,—each containing 18,000 square miles; 3. Adriatic, 40,000; 4. Ægean, 40,000; 5. Marmora Sea, 4000; 6. Black Sea, 160,000; 7. Sea of Azof, 10,000. Many important cities are on its shores, numerous large rivers flow into it, and several islands lie in it. The only remaining sea is the Caspian, containing 120,000 square miles, an inland sea, shallow on the shores, deep in the centre, containing no currents nor tides. It receives the waters of the Ural, Volga, and other rivers, and is subject to singular variations in size during long periods of time. It is no longer doubted that it was one with the Sea of Aral, and many geographers maintain that it was connected with the Mediterranean by way of the Sea of Azof. Its winds are variable and its storms terrific. Small vessels only navigate its waters, none larger than 150 tons. It is 330 feet below the level of the sea, and 100 feet below the Aral Sea. Properly speaking, it is a lake, but its great size leads it to rank with seas, while the name of sea for the Aral and Dead Seas is considered a misnomer. The Caspian Sea is less salt than the ocean, the fresh water brought in by its many rivers more than compensating for the very rapid evaporation. With the exception of Russia, the countries bordering on it are uncivilized, and no great cities are placed on it, and its commerce is small and less important for this reason.—*F. S. Bassett*, *Lieutenant U.S.N.*

Sea-adder. A British fish, of an elongated and slender form, with 15 short dorsal spines, and the entire lateral line covered with carinated scales; the *Gasterosteus spinachea*, or stickleback. The pipe-fish, *Syngnathus*.

Sea-anchor. The anchor lying toward the sea. A floating anchor used at sea in a gale. It is easily improvised by making a triangle of small booms, passing a sail between them, backing or thrumming it with rope, and fastening the cable to a bridle extending from the three apexes of the triangle. A more portable frame is made of two iron bars, joined at their centres so as to make the letter X, which may be shut up when not in use.

Sea-anemone. The *Actinia*, a polyp resembling a flower.

Sea-ape. The sea-fox. The otter.

Sea-attorney. The brown shark.

Sea-bank. A bank or mole to keep the sea from encroaching on the shore.

Sea-bar. The sea-swallow.

Sea-barrow. See Sea-pincushion.

Sea-bat. A kind of flying-fish.

Sea-beans. Acacia-pods, brought down by rivers, and found on beaches in southern waters.

Sea-bear. The polar bear. Seals of certain genera, as *Arctocephalus* and *Otaria*, using their hind fins in walking. See Seal.

Sea-beard. *Cladaphora rupestris*, a sea-weed growing in dense tufts.

Sea-blubber. A marine insect.

Sea-board. Land bordering on the sea; the sea-shore.

Sea-boat. A boat, considered with reference to her qualities or behavior at sea; as, a good, or a bad sea-boat.

Sea-borne. Afloat on the seas; water-borne.

Sea-bottle. The seed-pod of the *Fucus gigantea*, found in Horn latitudes.

Sea-bream. A sea-fish of the genus *Pagellus* (*Sparus* of Linnæus), growing to the length of from 16 to 20 inches, and used for food.

Sea-breeze. A breeze setting from the sea toward the land. See Breeze.

Sea-brief. See Sea-letter.

Sea-calf. The common seal, *Phoca*.

Sea-cap. White-caps, or wind-blown wave-summits.

Sea-card. An old name for a chart. The mariner's compass.

Sea-carp. A spotted marine fish, living among rocks and stones.

Sea-cat. The wolf-fish, *Ananhicas lupus*. A fish of the family *Chimœroidei*, intermediate between the sturgeon and the shark. The northern sea-cat (*C. monstrosa*) inhabits northern waters, and has green pupils, which shine at night like a cat's eyes. The southern sea-cat (*C. Australii*) has a snout turning back like a hoe, and is of a silvery color.

Sea-catgut. The sea-weed *Fucus filum*, or sea-thread.

Sea-chickweed. A marine plant, *Honkenya peploides*, growing in tufts in the sand.

Sea-coast. The shore or land washed by the sea.

Sea-cob. The sea-gull.

Sea-cocoanut. Cocoanuts from the palm, *Lodoicea seychellarum*, found in the Leychelle Islands. First found floating in the sea, they were thought to be fruit of the sea-weed.

Sea-compass. The mariner's compass.

Sea-coot. The coot (*Fulica*).

Sea-cormorant. The *sea-crow*.

Sea-coueter. The arctic puffin, *Fratercula arctica*.

SEA-COW. The manatee (which see).

SEA-CROW. The pewit gull, or *Xema ridifundus*. The cormorant.

SEA CROW-FISH. Crustacea of the genus *Palnurus*.

SEA-CUCKOO. The red gurnard, or *Trigla cuculus*.

SEA-CUCUMBER. The *bèche-de-mèr*, an echinoderm of the genus *Holothuria*. Salted and dried, it is eaten in China under the name of *trepang*. They are found in shallow water, and there are 8 genera, with 13 species on the American coast.

SEA-CUNNY. The helmsman in Lascar-manned East India vessels.

SEA-DAFFODIL. A bulbous plant, the *Pancratium maritimum*.

SEA-DEVIL. A fish of the ray family (*Cephaloptera*). The angler, or *Lophius piscatorius*.

SEA-DOG. The common seal. *An old salt;* a sailor long used to the sea.

SEA-DOTTEREL. The *Strepsilus interpres*, a sea-bird belonging to the plover family.

SEA-DRAGON. A marine fish of the genus *Cottus*.

SEA-DRAKE. See SEA-CROW.

SEA-EAGLE. The bald eagle. A large ray, with wing-like fins and a long tail, armed with a bone barb. It belongs to the genus *Myliobatis*.

SEA-EAR. A gasteropod mollusk of the genus *Haliotis*, green and violet inside, and resembling the human ear in shape.

SEA-EDGE. The bounding-line between the frozen and unfrozen regions of the pole.

SEA-EEL. The conger-eel.

SEA-EGG. The *Echinus*, or sea-urchin, after its spines are removed.

SEA-ELEPHANT. A large species of seal, the *Macrorhinus proboscideus*, growing to 30 feet in length, and having a fleshy snout about a foot long.

SEA-FARING. Following the sea as a means of livelihood.

SEA-FENNEL. The same as *samphire* (which see).

SEA-FERN. A kind of coral resembling a fern.

SEA-FIGHT. A naval action; an engagement at sea.

SEA-FISH. Salt-water fish. Any fish that lives usually in salt water.

SEA-FOWL. A marine fowl. A bird that lives by the sea and gets its food from salt water.

SEA-FOX. A species of shark, the upper lobe of whose tail is much longer than the lower, and curves upward. It frequently measures 13 feet in length, including the tail, which is then more than 6 feet long.

SEA-FROG. Same as *fishing-frog* (which see).

SEA-GAGE, or GAUGE. A form of sounding instrument, by which the depths are ascertained by the registered pressure of a liquid or vapor in the instrument.

SEA-GARLAND. A kind of marine plant.

SEA-GATE, or GAIT. A long, rolling swell. Ships that collide by its means are in a *sea-gate*.

SEA-GIRDLE. A marine plant, the *Laminaria digitata;* also called *sea-wand*, *sea-ware*, and *tangle*.

SEA-GODS. Deities supposed to have power over the sea. Principal among the Grecian deities were (1) Pontus, the father of sea-deities, and (2) Oceanus. The sons of Pontus were (*a*) Nereus, the god of the quiet sea; (*b*) Thaumas, god of the majesty of the sea; (*c*) Phorcys, (*d*) Ceto, (*e*) Eurybia, deities of the dangers and terrors of the sea. The sea-nymphs were the descendants of Oceanus. Aphrodite, born of the foam, was goddess of the sea, tutelary goddess of ships and mariners, and controlled the winds and waves, and gave good voyages. She was wife to Neptune, the principal god of the sea, who dwelt in ocean depths, and from thence controlled winds and waves. Sacrifices were made to him, especially by the Ionians in the temple at Corinth. One of his sons was Triton, and the Nereids, 50 daughters of Nereus, attend on him.

A favorite sea-deity was *Glaucus*, especially the god of fishermen and shipwrecked sailors.

SEA-GRAPE. The gulf-weed.

SEA-GRASS. An aquatic plant, the *Zostera marina*.

SEA-GREEN. A faint green. In ancient heraldry, the color denoted inconstancy.

SEA-GROCER (*Eng.*). An old name for the *purser*.

SEA-GULL. A sea-fowl, the *Xema ridibundus*. It is considered indicative of approaching bad weather for them to seek the shore in numbers, or to alight on ships at sea. To kill a gull is bad luck. Their stupidity is proverbial, and they are easily duped.

SEA-HARE. A marine gasteropod mollusk, the *Aplysia*.

SEA-HEATH. Evergreen plants of the genus *Frankenia*, found on sea-shores.

SEA-HEDGEHOG. The *Echinus*, or sea-urchin.

SEA-HEN. The guillemot, a sea-bird of the genus *Uria*. The crooner, a fish of the *Trigla lyra*.

SEA-HOG. The porpoise.

SEA-HOLLY. An evergreen plant of the genus *Eryngium*, found on the sea-shore.

SEA-HOLM. A small, uninhabited island.

SEA-HORSE. The walrus. The hippocampus, a fish having a prehensile tail.

SEA-KALE. An edible plant, the *Crambe maritima*, found on the sea-shore; sea-cabbage; sea-colewort.

SEA-LAKE. A lagoon.

SEA-LARK. A sand-piper. The ringed dotterel.

SEA-LAWS. See MARITIME LAW, OLERON CODE, RHODIAN LAWS.

SEA-LAWYER. An idle, querulous sailor, given more to questioning orders than to obeying them; one disposed much to argue the question. The tiger-shark.

SEA-LEGS. Ability to walk on the moving deck at sea. *To get sea-legs on*, to become accustomed to the motion, so as to walk on the deck.

SEA-LEMON. A marine gasteropod mollusk of the genus *Doris;* it is lemon-colored, oval, and marked with numerous punctures.

SEA-LEOPARD. A seal, the *Stenorhynchus leopardinus*, spotted like a leopard.

SEA-LETTER. A document issued by the civil authorities of the port in which a vessel is fitted out, and a certificate of the nationality of the vessel. It specifies the nature, quantity, ownership, and destination of the cargo.

SEA-LION. A large seal of the genus *Platyrhynchus*, having a mane like a lion. See SEAL.

SEA-LOG. That part of the log book relating to the ship while at sea.

SEA-LOUSE. A crab, the *Pediculus marinus*.

SEA-MAID. A mermaid or sea-nymph.

SEA-MALL. The mew; a sea-gull.

SEA-MARK. Any object, as a beacon, steeple, chimney, tree, or hill, easily distinguishable from to seaward, and used as a guide in the piloting of a vessel.

SEA-MEN. Same as SEA-MALL.

SEA-MOUSE. A marine annelid, the *Aphrodita aculeata*, covered with long iridescent hairs.

SEA-NAVEL. A small shell-fish.

SEA-NEEDLE. The sea-pike, or gar (*Belone vulgaris*), with long pointed jaws and a forked tail.

SEA-NETTLE. All *Acalephæ*, particularly the *Medusæ*, that have the property of stinging.

SEA-NYMPH. A nymph or inferior goddess of the sea.

SEA-ONION. A sea-coast plant, the *Scilla maritima*.

SEA-OOZE. Soft mud near the shore.

SEA-ORB. A round marine fish.

SEA-OTTER. An aquatic mammal, the *Enhydra marina*, found in the North Pacific Ocean.

SEA-OWL. The lump-fish.

SEA-PAD. The star-fish.

SEA-PANTHER. A fish like a lamprey.

SEA-PASS. See PASSPORT.

SEA-PAY. The pay received or due for actual service in a sea-going ship.

SEA-PERCH. Salt-water perch.

SEA-PHEASANT. The pin-tail duck, *Dafila caudacuta*.

SEA-PIE. A sea-fowl, the *Hæmatopus ostralegus*, also called the oyster-catcher, from its thrusting its bill into open oysters and eating them. A dish composed of fish or meat and vegetables in layers between crusts, the number of which decide whether it is a *double-decker* or a *three-decker*.

SEA-PIKE. The gar-fish.

SEA-PINCUSHION. A star-fish, of the genus *Goniaster*.

SEA-PINK. A marine plant, the *Cerastium repens*.

SEA-POACHER. The pogge, or *Catophroctus Schonœldii*.

SEA-PORCUPINE. This name is given to several fish of the genera *Diodon* and *Tetraodon*, whose bodies are thickly covered with spines. Their flesh is poisonous, and one species gives electric shocks if touched.

SEA-PORK. The flesh of young whales.

SEAPORT. A haven on the sea.

SEA-PUDDING. A species of holothurian.

SEA-PURSE. See MERMAID'S PURSE.

SEA-PURSLANE. A marine plant of the genus *Sesurium*.

SEA-QUADRANT. A name for the *Jacob's staff*.

SEA-QUAKE. A quaking or shaking of the sea.

SEA-RATE. See CHRONOMETER.

SEA-RAVEN. The *sculpin*, a fish of the genus *Hemitripterus*.

SEA-REACH. The straight lower course of a winding river emptying into the sea.

SEA-REED. A grass (*Calamagrostis arenaria*) found on the sea-shore.

SEA-RISK. Hazard or risk incurred by passage at sea.

SEA-ROBIN. The gurnard, a fish of the genus *Trigla*.

SEA-ROCKET. A plant of the genus *Cakile*, growing on the shore.

SEA-ROKE. A cold fog or mist, spreading from the sea inland.

SEA-ROOM. Ample space at sea to drive or scud without danger.

SEA-ROVER. A sea-robber; a pirate.

SEA-SCORPION. A voracious marine fish, the *Cottus scorpius*, having its head armed with spines.

SEA-SERGEANTS. A Welsh secret society, existing from 1726 to 1765.

SEA-SERPENT. A fabulous animal continually rediscovered at sea. A Mediterranean eel. A large Australian marine serpent, the *Hydrus Stokesii*. The stories of the sea-serpent were mythological in origin, coming from the north of Europe, but many scientists have acknowledged the possibility of the existence of *Saurians*, or sea-reptiles of great size.

SEA-SHORE. The coast of the sea. In law, the land between low- and high-water marks.

SEA-SICKNESS. Vomiting caused by the motion of a vessel or boat. The premonitory symptoms are vertigo and headache, with a peculiar feeling of sinking and distress about the pit of the stomach, which is soon followed by a profound nausea accompanied with convulsive heaving of the stomach and utter prostration of the entire body; a deadly pallor and profuse cold sweat are commonly present.

SEA-SLATER. The *Ligia oceanica*, a small shell-fish.

SEA-SLEEVE. The squid, *Loligo vulgaris*.

SEA-SLUG. The sea-cucumber, or *Holothuria*.

SEA-SNAIL. A fish found under stones near the sea-shore, belonging to the genus *Liparis*.

SEA-SPIDER. A crab with a triangular body and long, slender legs, the *Maia squinada*.

SEA-SPOUT. The spouting of water through a cleft in a rocky cliff.

SEA-STAR. The star-fish.

SEA-STREAM. A polar term, indicating a collection of bay-ice, affording shelter behind it from the ocean.

SEA-SWABBER. A term of reproach for an idle sailor.

SEA-SWALLOW. The tern, *Sterna hirundo*. The storm-petrel, *Procellaria pelagica*.

SEA-SWINE. Porpoises.

SEA-TANG. Tang, or sea-weed.

SEA-TOAD. An ugly sea-fish.

SEA-TRANSOM. The stern-transom bolted to the ends of the counter-timbers.

SEA-TURN. A breeze, gale, or mist from the sea. A tack to seaward.

SEA-UNICORN. The narwhal. See NARWHAL.

SEA-URCHIN. The *Echinus*. See SEA-EGG.

SEA-WALL. A wall built to prevent the sea from overflowing inclosed lands.

SEAWARD. Toward the sea.

SEA-WARE. Sea-weed thrown on the beach.

SEA-WATER. The water of the ocean varies greatly in its component parts in different localities. The solid parts contained therein are chlorides of sodium, potassium, and magnesium, bromide and sulphide of magnesium, carbonate of lime and magnesium, ammonia, silver, and traces of other metals. Water from the Mediterranean contains 410 parts in 10,000; from the English Channel, 380 parts; from the North Sea, 312 to 360 parts; and from the Baltic, 66

to 216 parts. The average of solid parts is 3½ per cent., and the average specific gravity is 1.0274. The water of the Dead Sea is really a mineral water, being 25 per cent. of solid parts.

SEA-WEASEL. The *lamprey eel.*

SEA-WEED. See ALGÆ.

SEA-WIFE. A fish of the genus *Labrus.*

SEA-WILLOW. A polyp belonging to the genus *Gorgonia.*

SEA-WOLF. The wolf-fish. *Anarrhicas lupus*, found in northern seas about Greenland, Iceland, Norway, Scotland, England, etc., and so named from its fierceness and ravenousness. It grows sometimes to the length of 4, and even 7 feet, and feeds on crustaceous animals and shell fish, as well as on common fish. A kind of seal. See SEAL.

SEAWORTHY. Fit in every way to make a voyage at sea. Staunch and tight.

SEA-WRACK. Sea-weed and grass thrown on shore on the coast of Holland, and used for manuring land (*Zostera marina*).

Seal. An aquatic carnivorous mammal of the family *Phocidæ.* They subsist on fish, and are abundant in the colder waters of the globe. The following are the most important genera and species: The genus *Callocephalus*, or *Phoca*, the common seal, *C. vitulinus*, belonging to it. It is common in European and American waters, and is valuable for its oil, furs, and skin. It is from 4 to 6 feet long. The *P. barbata*, or bearded seal, is found on icebergs in the open Polar Sea, and attains a length of from 10 to 12 feet. The Greenland seal, *P. Grœnlandica*, is found in herds on floating ice; is most useful to the Esquimaux for its oil, flesh, and skin, and fur; is but 6 feet long. The hare seal, *P. leporina*, is from 6 to 7 feet long, and is found about the northern shores of Europe. Another genus is *Halichœrus.* To it belong the *H. griseus*, or gray seal, and the *H. Caspica*, or Caspian seal, found in the Caspian Sea, and valuable for its excellent oil. To the genus *Stenorychus* belongs the *sea-leopard*, and to the genus *Pelagius*, the monk seal, or *P. monachus*, white-bellied, from 8 to 10 feet long, found in the Adriatic and Mediterranean Seas. To the genus *Stemmatopus* belongs the crested seal, *S. cristatus*, 7 to 8 feet long, which has a membranous sac on its head, capable of inflation. It is found on the coast of Labrador. The largest seal, the *elephant seal*, belongs to the genus *Macrorhinus* (*M. proboscideus*), and attains a length of 25 feet. Its oil is quite valuable. Many seals belong to the genus *Otaria*, also known as *Platyrhynchus* and *Arcto-cephalus.* The sea-lions and sea-bears belong to this genus. There is a northern sea-lion (*O. Stelleri*) and a southern sea-lion (*O. Jubata*), as well as a northern sea-bear (*O. Ursina*) and a southern sea-bear (*O. Irorsteri*), the latter nearly extinct.

Sealed Orders. Orders sealed, only to be opened at a certain time, for instance, after the ship is at sea, to prevent their being divulged.

Seam. The openings between the planks of the deck and sides of a ship, that are filled with oakum and pitch in calking. The junction of two pieces of canvas, when they are sewed together. Sails, awnings, etc., are sewed with different seams, varying with circumstances. A *flat seam* is one in which two edges of canvas are overlapped two inches, and then each edge is stitched to the other piece by a direct seam. When old canvas is restitched, it is sometimes necessary to *middle stitch* a flat seam, by running a seam midway between the other two. A *round seam* is one in which two edges of cloth are brought together, and stitched together by overcasting the thread. A *cord seam* is one in which the edges are again brought together, as in the round seam, but are slightly rolled in on the cloth, and stitched to it. From 3 to 4 stitches an inch are taken.

Seaman. A mariner; a sailor. Properly, one competent to perform all the duties of the profession, whether man or officer. The grade of seaman, or able seaman, recognized in all navies, comprises those who are practically conversant with all the duties of common seamanship; as, to reef, to hand, to steer, to heave the lead, to rig the spars, sails, etc. In the U. S. navy they are paid $21.50 per month; in the English navy, from $6 to $7. *Ordinary seamen* are those only partially skilled in these duties.

SEAMAN-GUNNER. Seamen who are particularly trained in gunnery duties, forming a distinct grade in many navies. The grade was created in the U. S. navy, but is fast becoming extinct.

SEAMAN'S DISGRACE. A foul anchor.

Seamanship. The practical science and art of rigging, fitting, manœuvring, and handling a ship or boat.

Searcher. A customs-officer. An instrument for examining the bore of guns.

Seasoned Timber. Timber prepared for use by preservation in air, water, or by chemical processes for a certain length of time.

Seasoning a Ship. Allowing a ship to stand before she receives her planking, so as to dry out the timbers.

Seat. In mechanism, an accurately fitted portion of a frame or relatively fixed piece on which another piece bears, rests, or is secured; as, the *seat* of a bracket or flange, or a *valve-seat.*

Seat-lockers. Lockers arranged so as to form seats in the cabins, etc.

Secondary Circles. Great circles of the sphere passing through the poles of another great circle, which is called their *primary.*

Secondary Meridians. Meridians of the earth which are determined like the *first*, *prime*, or *primary* meridians, such as those of Greenwich, Paris, etc., by astronomical or absolute evidence, independently of the chronometrical or relative method. The primary meridians are those from which the longitudes in the tables and on the charts are reckoned; the secondary meridians are useful as fundamental and independent starting-points in making passages.

Secondary Planet. See PLANET.

Second Captain. A commander in a ship under a captain, in some navies.

Second Differences. See DIFFERENCES, SECOND.

Second Futtocks. The timbers of the frame next above and joined to the first futtocks, or to the floor-timbers.

Second-hand. The second in charge of a fishing-boat.

Second Lieutenant. A term often employed to designate the officer next in rank to the executive-officer; the navigator. The lowest grade of commissioned officers in the marine corps, ranking with an ensign in the navy.

Second Officer. The second mate of a merchant vessel.

Second-rate. The second of the grades into which ships of war are divided. See CLASSIFICATION.

Secret Block. A block with a lignum-vitæ shell, open only at two orifices sufficiently large to allow the rope to pass through that is to work around the sheave.

Secretary. A rank in the navy corresponding with lieutenant, bestowed on the person employed as the private clerk or amanuensis of the admiral and of the vice-admiral. An officer detailed to serve as clerk to a flag-officer, usually ranking with lieutenant. The chief or confidential writer to the commandant of a naval station. See NAVY DEPARTMENT.

Sectional Dock. A form of floating dock, made in sections. Each section is a tank having trestle-work on the sides to which the shores are secured Outside the tanks on each side are floats made of sufficient capacity to impart the proper stability to the tank when the vessel is raised; on the top of the trestle-work is a walk or platform upon which the machinery used in pumping the dock is placed. It has an advantage over the docks for light and air, and can be used or floated anywhere where there is sufficient water.

The tanks and blocks of an ordinary sectional dock require fifteen feet more water than the ship which is intended to be raised. For this reason alone a basin dock is better for most purposes.

Secunda Giedi. The star α^2 *Capricorni.*

Secure! A command in exercising or working heavy guns, meaning to so arrange the breeching and tackles that the gun shall be in no danger of breaking loose in a sea-way. Guns are secured more thoroughly for sea than for port.

Securing-bolts. Eye-bolts placed in the ship's side, nearer to the port than the fighting-bolts, in which the outer blocks of the tackles are hooked when the gun is secured.

Sediment Collector. A perforated inverted cone, placed at the mean water-level of a marine steam-boiler, to the apex of which the surface blow-pipe is attached. It is not found efficient in practice.

A cylindrical drum, attached to the bottoms of Western-river steamboat boilers, to which the *mud blow-off pipe* is connected.

Sedow. The *gilt-head* (*Sparus auratus*).

Seeling. Sudden heeling over, and return to an upright position.

Segment-shell. A rifle-shell, having a thin outer shell lined with segmental pieces of cast iron, to separate at explosion.

Seize. To fasten ropes to each other or a rope to any object by regular turns of a small line.

SEIZINGS. These are of various kinds, according to their position and use. An *eye-* or *throat-seizing* is one or two parts of a rope that cross to form an eye. A *round seizing* has *riding* or *upper* turns over the first layer. A *flat seizing* has but one layer of turns.

SEIZING-STUFF. *Small-stuff* is used for seizings, *foxes* and *rope-yarns* for temporary seizings, *marline*, *hambroline*, *houseline*, *round line*, etc., for permanent seizings. Seizing-stuff is 9-, 6-, or 4-thread stuff, of tarred hemp yarns.

Selaciun. One of a tribe of cartilaginous fishes, including the ray and the shark.

Selchie. The seal, *Phoca vitulina.*

Self-fastening Rowlock. A metal rowlock, whose socket travels in a tube, so that it fastens itself in on reaching the bottom of the tube.

Self-mousing Hook. A hook closing automatically by means of a tongue, so that it will not slip.

Selfridge, Thomas O., Rear-Admiral U.S.N. Born in Massachusetts. Appointed from Massachusetts, January 1, 1818.

Commissioned as lieutenant, March 3, 1827; Exploring Expedition, 1829; sloop "Natchez," West India Squadron, 1830; frigate "Delaware," Mediterranean Squadron, 1834; frigate "North Carolina," 1837; rendezvous, Boston, 1840.

Commissioned as commander, April 11, 1844; navy-yard, Portsmouth, N. H., 1845; frigate "Columbus," East India Squadron, 1846; commanding sloop "Dale," Pacific Squadron, 1848; commanding rendezvous, Boston, 1851–52; Boston Navy-Yard, 1853–55.

Commissioned as captain, September 14, 1855; commanding steamer "Mississippi," 1861; commandant Mare Island Navy-Yard, Cal., 1862–64.

Commissioned as commodore, July 16, 1862. Retired October 10, 1866; commandant navy-yard, Philadelphia, 1867–68; president Examining Board, 1869.

Commissioned as rear-admiral, July, 1870.

Selvagee. A rough rope, made of a bundle of rope-yarns wound round or marled with another yarn.

SELVAGEE STRAP. A strap made of selvagee, used in securing the breeching of guns, etc.

Semaphore. An upright post with movable arms, for making signals.

Semidiameter. Half the angle subtended by the diameter of the visible disk of a heavenly body at the eye of the observer.

Semimenstrual Inequality. An inequality of the tide, which goes through its changes every half-month.

Send. To pitch violently into the trough of a sea. To 'scend.

Senior Officer. The commanding officer, or the most advanced line-officer in rank at any time or place.

Sennit. Flat cordage, formed by plaiting rope-yarns or thread together. They must be of an odd number, and hence the name, *seven-knit.* There are several kinds. *Common* or *flat sennit* is plain plaiting, five to seven strands being used. *French sennit* is similarly made, but more strands are used, and it is more open, forming a woven band of yarns. *Round sennit* is formed by plaiting even numbers of strands in twos around a small rope or *heart. Square sennit* is made of even-numbered strands without a heart. Sennit of grass was formerly woven into hats by sailors, but is so no longer.

Sensible Horizon. See HORIZON.

Sentry, or Sentinel. A marine or seaman placed on post charged to guard certain property, or carry out certain orders. On board ship, marine sentries are stationed at gangways, cabin doors, over prisoners and scuttle-butt, and on the forecastle and poop.

Serang. The boatswain of a Lascar crew.

Serpens (*Lat.* "The Serpent" of Ophiuchus). A constellation lying to the east of the line joining Arcturus and Antares.

Serpent-fish. A fish with a body of a ribbon-

like and compressed form, and a band of red running lengthwise, *Cepola rubescens*.

Serpentine. An old 24-pounder, 13 feet long, weighing 4300 pounds.

Serve. To perform duty on board ship or in government establishments, or under orders. To cover a rope closely with smaller stuff, so as to protect it from the weather. Rope is first *wormed*, then *parceled*, then *served*. *To serve the vent*, to clear with the priming-wire before loading.

SERVICE. The small-stuff wound around a rope to protect it from the weather.

SERVING-BOARD. A flat piece of hard wood, having a handle attached, used in serving small ropes.

SERVING-MALLET. A short mallet, with a groove on the under side, used in serving large ropes.

SERVING-STUFF. Spun-yarn is generally used, but hambroline, houseline, and round line are sometimes preferred.

Set. The direction in which a current flows. A suit, or complete number, as a set of signals. To observe and note the bearings of any object by the compass. *To set sail*, to put to sea. *To set a sail*, to spread it. *To set the chase*, to observe well the bearing of a vessel chased. *To set the course*, to prescribe the course to be steered. *To set the watch*, to call and formally report the night-watch at 8 P.M. *To set up rigging*, to take in the slack of the standing rigging, so as to give a better support to the masts. *Setting up a ship*, raising her from the keel-blocks by wedging.

Set-bolt. A bolt used as a punch or drift to force a bolt farther in than can be done by driving; it is also used to drive out bolts. A bolt to force planks together.

Set-screw. A screw binding or clamping an adjustable piece, when *set* or adjusted, in a desired position, to another relatively fixed piece, such as a shaft, bar, or portion of a frame; as, the *set-screw* of a *collar*, *eccentric*, *wheel*, *slide*, etc.

Sett. A power used by shipwrights; two ring-bolts with a staff, fastened by cleats and lashings.

Settee. A vessel used in the Mediterranean, with a very long and sharp prow, and with lateen-sails.

Setting-pole. An iron-shod pole, to move a boat with in shallow water.

Severalty. A law-term, indicating the reference of disagreements among part-owners of a ship, or her cargo, to the courts.

Sew. To cant or heel when left on the sand by the tide.

Sewant. The plaice.

Sewin. A salmon taken in Welsh waters.

Sextans. See CONSTELLATION.

Sextant. The sextant (Lat. *sextans*, the sixth part) is a portable instrument for measuring angles by reflection, and is very generally used by navigators and surveyors for measuring the altitudes of heavenly bodies, the angular distance between them, and, in place of a theodolite, the horizontal angular distance between terrestrial objects. The instrument was invented by Sir Isaac Newton, who, however, did not publish his invention, which was subsequently made independently by Mr. John Hadley, an Englishman, and by Mr. Thomas Godfrey, a Philadelphian. The principle governing the construction of the sextant is, that "the angle between the first and last directions of a ray of light which has suffered two reflections in one plane is equal to twice the inclination of the reflecting surfaces to each other."

The sextant, held in the hand and requiring no fixed support, is peculiarly adapted to use on shipboard. For measuring altitudes at sea the line of the apparent horizon is used, but on shore, where various objects hide the natural horizon, an artificial horizon is used, consisting usually of a flat dish of mercury with a glass cover. The image of an object seen by reflection from the surface of the mercury, appears as much below the horizon as it is really above it, so that the angle between the object itself and its reflected image is double its altitude above the horizon. Attempts have been made to invent a device which would take the place of the sea-horizon when it was hidden by fog or haze, but thus far without much success.

With ordinary sextants no angles greater than about 120° can be measured, but with the admirable prismatic sextant of Messrs. Pistor & Martins, angles up to 180° may be accurately measured. In this instrument the index-glass of the ordinary sextant is replaced by a rectangular prism, and rays from the object seen directly come to the telescope without passing through any medium, such as the unsilvered portion of the horizon-glass. As both the reflected and direct objects are much better defined than in the ordinary instruments, this sextant is peculiarly well adapted for determining latitude by altitudes of stars on shore with the artificial horizon.—*F. M. Green*, *Lieutenant-Commander U.S.N.*

SEXTANT, ADJUSTMENT OF. The index-glass must be perpendicular to the plane of the arc. The horizon-glass must be perpendicular to the plane of the arc. The necessary adjustments are made by screws at the back of the mirrors. The line of collimation of the telescope must be parallel with the plane of the arc. The adjustment is made by means of the screws on the collar of the telescope. When the index-glass and horizon-glass are parallel, the index should coincide with 0 on the arc. The sextant need not be adjusted on account of this error, if the proper allowance is made on each observation.

Shackle. An iron link, one end of which is closed by a movable bolt. *Screw-shackle*, a shackle in which the bolt is screwed into place.

SHACKLE-BOLT. The large iron bolt that closes a shackle when in place.

SHACKLE-BLOCK. A block with an iron strap terminated by a shackle and bolt.

SHACKLE-NET. A flue-net.

SHACKLE-PIN. The small pin that confines the shackle-bolt in place. Wooden pins are generally used.

SHACKLE-PUNCH. An iron punch for driving out shackle-bolts.

Shad. Fish of the genus *Alosa*.

Shades. Sets of colored glasses fitted to reflecting instruments to diminish the glare of bright objects.

Shaft. In machinery, a long cylindrical or prismatic piece, which revolves or oscillates about its axis on journals fitted to suitable bearings, for transmitting to a wheel, lever, or other piece a rotative, oscillating, or reciprocating rectilinear

motion at any part of its length. Small and rapidly revolving shafts are called *spindles.*

A *counter-shaft* is a short shaft through which motion is transmitted by belts from line shafting, or the shaft of a prime mover to a working machine or tool, such as a lathe, planing-machine, saw, blower, etc. It is provided with a fixed and a loose pulley, and means for shifting the belt of the driving-pulley from one to the other, so that it may be set in motion or at rest at will, and with a pulley, drum, or speed-cone belted to corresponding parts of the driven machine. When it is required to suddenly reverse the motion, as with a screw-cutting lathe, two loose pulleys, driven in opposite directions by a pair of belts, one of which is crossed, are used; the motion being communicated to the shaft by a *sleeve* and *clutch.* The speed of the machine is determined by the relative sizes of the pulleys; and a *speed-cone* is used when varieties of speed are required.

An *intermediate shaft* is used for transmitting motion from one shaft to another when their relative positions will not admit of direct connection, or when the difference in speed is such as to require inconvenient sizes of wheels or pulleys; also, for preserving motion in the same direction of two shafts connected by toothed wheels or gearing.

Line shafting is a long, continuous line of sections of shafting held together by couplings; as, a *screw-propeller shaft*, or the *line shafting* of a factory.

SHAFT-ALLEY. A passage extending from the engine-room to the stern stuffing-box, in which is contained the propeller-shaft and its bearings.

SHAFT-BEARING. A support for the journal of a shaft. See BEARING.

SHAFT-COUPLING. A piece, or pair of pieces, for securing sections of shafting together. See COUPLING.

SHAFT-PIPE. The pipe, of copper or iron, placed in the dead-wood of a screw-ship as a lining; having glands or a proper packing at each end, it can be made water-tight.

Shag. The green cormorant, *Phalocrocorax graculus.*

Shake. *To shake out a reef*, to let it out and enlarge the sail. *To shake a cask*, to take it to pieces and pack the staves. These are called shakes, and hence the term "*no great shakes.*" *To shake the sails*, to luff up in the wind, causing the sails to shiver. A *shake* among shipwrights is a crack or rent in timber. *Shake a leg!* hurry up! be quick!

Shakings. Refuse of cordage, canvas, etc. Oakum swept up off decks.

Shallop, or Shalloop. A small boat rowed by two men. A light fishing-boat, with small fore- and main-lug sails. The term is also applied to *sloops.*

Shallows. Large extents of shoal water.

Shallow-waisted. A term opposed to *deep-waisted*, applied to flush-deck vessels.

Shan. Knotty or fibrous defects in timber.

Shang-Hai, the chief emporium of China, now open for European commerce, is situated in the province of Kiang-Soo, on the Woosung River, and 12 miles above the mouth of the Woosung, in the estuary of the Yang-tse-Kiang. The river, though three-quarters of a mile broad opposite Shang-Hai, is little better than a mere tidal channel. It is an important entrepôt of the commerce between the north and south provinces of China, exporting manufactured goods to Tien-Tsin, and importing large quantities of pulse, flour, meats, rhubarb, and skins from the shores of the Yellow Sea. It has an extensive river trade with the interior of China, and its coasting trade is also very large. It has regular steam communication with all the open ports of China and Japan, and with India, the United States, and Europe. About 2000 vessels clear port here annually, and the value of the imports and exports is about $75,000,000 each year. Lat. 31° 12′ N.; lon. 121° 28′ E. Pop. 250,000.

Shank. An arrangement of deep-sea fishing-lines. The main piece of an anchor, connecting the stock and the arms.

SHANK-PAINTER. A rope or chain which confines the shank of the anchor to the bill-board.

Shanny. A small fish (*Pholis subfurcatus*), which lurks under stones and weeds.

Shape. *To shape the course*, to determine the course which the ship is to steer.

Shark. Cartilaginous fish of the family *Squalidæ.* They are carnivorous and very voracious. There are some 100 species, varying greatly in size, from 3 feet to 40 feet in length. The *Scyllidæ* contains the *dog-fishes*, and they all spout. The white shark (*Carcharias vulgaris*) and the blue shark (*C. glaucus*) belong to this family. The basking-shark is the largest, and belongs to the genus *Selache.* It attains a length of 40 feet. The thresher-shark belongs to the genus *Alopia;* the *angel-fish*, *monk-fish*, or *fiddle-fish*, to the *Squalidæ.* The *hammer-headed* shark belongs to the *Zygænidæ.*

Sharks vary somewhat in their habits, many kinds being dangerous to man, while others are comparatively harmless. The name *shark* is also applied to crimps, sharpers, and low attorneys.

SHARK'S-MOUTH. The opening for the breeching at the cascabel of a gun. The irregular opening cut in an awning to embrace the mast.

Sharp. Prompt and ready. *Be sharp!* make haste! *Look sharp!* be quick! A sharp is one versed in some specialty, as a torpedo-sharp, a gunnery-sharp, etc. A yard is *sharp-up* when it can be braced up no farther. *Sharp-bottom*, a sharp floor, or one with considerable rise in the timbers. *Sharp-iron*, a calking-tool.

Sharpie. A long, flat-bottomed sail-boat, used in the United States.

Shear. An iron eel-spear. A stress tending to separate a body into parts, overcoming the cohesion of its particles by sliding one part over another in a plane parallel to the direction of the force.

Shear-bill. A sea-fowl, the *Rhynchops nigra.* The cutwater, or black skimmer.

Shear-hooks. A kind of sickle, formerly placed at the yard-arms to cut the rigging of an enemy on boarding her. They are described by Vegetius in his "Re militaris," and were extensively used in the 14th, 15th, and 16th centuries, and even as late as the 17th century they were seen.

Shears. See SHEERS.

Shear-water, or Shear-water Petrel. A sea-fowl, the *Puffinus Anglorum.*

Sheat-fish. See SHEET-FISH.

Sheathing. The casing or covering placed on a ship's bottom for protection. The material for

such covering. Ships were formerly *breamed*, or charred, for this purpose, but this afforded slight protection. Wood sheathing was also used. Lead was introduced in 1620, the sheets being fastened by copper nails. This lasted until 1770, the "Marlborough," English line-of-battle ship, wearing hers entirely off. With wood sheathing nails were sometimes used with heads so large as to meet and cover the sheathing. A coating of tar, pitch, and brimstone was used in 1737, and was quite successful. A Japanese junk of 800 tons was seen in Japan, in 1613, iron-sheathed. In 1761, copper was first applied as sheathing. Galvanic action was the greatest obstacle, and it led to the use of copper bolts. Compounds of copper with other metals have been used, chief among which are the following: Muntz's metal—copper, 60, zinc, 1 part; Mushet's metal—copper, 100, zinc, ½; Revere metal—copper, 95, zinc, 5; Wethersted metal—copper, 90 to 97, antimony, 3 to 10; Collins's red—copper, 8, zinc, 1; Collins's yellow—copper, 10, zinc, 8; Collins's white—copper, 1, zinc, 16, tin, 16; Pope's metal—lead, 1, zinc, 3, tin, 2 parts. Copper is put on with after and under sides lapping, and the sheets are of various sizes, shown by the weight in ounces to the square foot, being 16, 18, 28, and 32 ounces.

SHEATHING-NAILS. Large flat-headed metal nails, used to nail on sheathing. They are from ¾ to 2½ inches long, and have large flat heads.

SHEATHING-PAPER. Thick, coarse paper put on under the sheathing.

Sheave. The wheel on which the rope works in a block, or in a mast or yard. They are of hard wood, generally of lignum-vitæ, or of brass or iron. Sheaves are open or solid in make, when of metal. A *dumb-sheave* is simply a groove in the heel of a topmast for a hawser to lie in. A *patent-sheave* is one having at its centre a brass frame carrying several small brass rollers, inside which the pin is put. The friction is absorbed by the rollers. A layer of tiers in a coiled rope is a *sheave*.

SHEAVE-HOLE. An aperture cut in a block, mast, or yard, in which a sheave is fitted.

Shebeen. A low groggery frequented by sailors.

Shedders. Female fish during the spawning season.

Sheen-net. A large drag-net.

Sheep-shank. A hitch made in a rope for the purpose of shortening it temporarily. It is made by taking two long bights in a rope, and half hitching each part over an end of this loop.

Sheepshead. A fish caught on the shores of Connecticut and of Long Island, so called from the resemblance of its head to that of a sheep (*Sparus ovis*). It is allied to the gilt-head and sea-bream, and is esteemed delicious food.

Sheer. The upward longitudinal curve of a vessel's deck or sides. The position in which a ship is kept when at anchor, to keep her clear of her anchor. *To sheer off*, to avoid a danger by turning the ship's head away from it. *To break the sheer*, to be forced by wind or wave over the anchor, so as to be in danger of breaking it out.

SHEER-BATTEN. A long and wide batten used in running the sheer-lines upon the ship while building.

SHEER-LINE. See LINE.

SHEER-PLAN. The vertical longitudinal plan of a ship. See PLAN.

SHEER-POLE. An iron rod, fastened to the shrouds just above the dead-eyes, to which the *ratlines* are parallel.

SHEER-RAIL. A rail, molded on the outside, placed along the topsides.

SHEER-SAIL. A drift-sail.

SHEER-STRAKE. In merchant ships, the upper strake, or that strake upon which the plank-sheer rests. In vessels of war, the strake worked above the ports and nearest to the deck, and which forms the chief strength of the topsides.

SHEER-WALES. The same as *middle-wales*.

Sheers. Sheers consist of two or more spars raised at an angle, lashed and supported by guys, and having purchases attached by means of which masts are raised, or any other heavy weight lifted. *Stationary sheers* are erected in navy-yards, and are of various patterns, the most ordinary kind being two inclined spars, supported by ropes or chains, and two breasting spars or skids. Movable sheers are temporary structures erected on board a ship for the purpose of moving her masts. (See MASTING.) Sometimes sheers are erected on a movable vessel, called a *sheer-hulk*. Sheers are often replaced by heavy cranes worked by steam.

SHEER-HULK. An old ship fitted with sheers, etc., for masting. Figuratively, an old sailor worn out in the service.

SHEER-LASHING. A lash passed about the head of the sheers.

SHEER-MAST. A mast made of two spars like sheers, inside which a yard works. Used on Peruvian boats.

Sheet. A rope or chain fastened to the lower corner of a sail, to haul and keep it in place. A *course* has a sheet and a tack at each lower corner. When before the wind, both sheets are hauled aft, but only the lee sheet under other circumstances. Other square-sails use both sheets when the sail is set. The stay-sail, jibs, and try-sails have a sheet at their lower after corner only. The studding-sails have two sheets at their lower inner corner only. The sheets are all named after the sails which they extend. *Sheet home!* An order to haul on the sheets of a sail, until the sail is as close to the yard, boom, or deck as it may be. A *sheet in the wind*, half-tipsy, fuddled. *Both sheets in the wind*, very drunk.

SHEET-ANCHOR, or WAIST-ANCHOR. An anchor stowed on shores in the waist outside the ship, in the wake of the fore-sheet, on either side. Formerly the sheet-anchor was the heaviest. By the allowance-book, bowers and sheets are of the same weight in the navy.

SHEET-BEND. A bend made by passing the end of a rope through a bight in another, round both parts and under its own part.

SHEET-BITTS. Bitts for the sheet-chain. Bitts near the mast, to belay the topsail-sheets to.

SHEET-CHAIN, or SHEET-CABLE. The cable or chain used with the sheet-anchor. They are furnished to the navy 15 fathoms shorter than the bower-cables, but of the same diameter.

Sheet-fish. A large fish, the *Siluris glanis*.

Sheet Flue-boiler. A boiler in which the flues are made of sheets or plates riveted together. The cross-section of the flues may be circular, rectangular, oval, or of any arbitrary form.

Sheets. The sheets of a boat are the spaces in the forward and after ends, unoccupied by rowers, called the *fore-sheets* and the *stern-sheets.*

Sheldrake. The duck, *Tadorna vulpanser.*

Shelf. A sand-bank bounded by a ledge of rocks. A shelf-piece.

Shelf-pieces. Strakes of thick plank, running along inside the ship, to support the ends of the beams.

Sheliak. The star β *Lyræ.*

Shell. A hollow iron shot containing explosive materials, destined to burst at the proper time by a charge contained in it. Powder is generally used for this charge (called the bursting charge), but dynamite and other powerful explosives have been suggested. (See PROJECTILES.) The outside case or envelope of a marine boiler. It is entirely of iron or steel. (See MARINE BOILERS.) The wooden or metal casing covering the sheave of a block. *To shell*, to throw shell into a place so as to thoroughly bombard it.

SHELL-BAG. A bag used for carrying or hoisting shells in on board ship, or for stowing empty shell in.

SHELL-BEARER. A wooden or iron implement for carrying heavy shell.

SHELL-CRANE. An iron stanchion shipped at or near a hatch, for hoisting shell from below.

SHELL-EXTRACTOR. A part of the machinery of a breech-loading rifle, designed to remove the empty shell after each fire.

SHELL-GAUGE. Callipers to gauge the dimensions of shell.

SHELL-GUN. A gun designed particularly for throwing shell.

SHELL-HOUSE. A house on shore for the stowage of shell.

SHELLMAN. One of a gun's crew who provides the gun with shell. In each gun's crew there are two shellmen.

SHELL-POWDER. Powder used for filling shells. It is now the same as *torpedo* powder.

SHELL-ROOM. A room below the berth-deck, constructed and lighted like a magazine, and used to stow loaded shell in.

SHELL-STRAP. An iron strap used to fasten the sabot to the shell.

SHELL-WHIP. A light tackle to whip up shell from below. In monitors, the upper block runs on a bar above, so as to be brought to the muzzle of the gun, or over the shell-room hatch.

Shellac. Melted resin- or gum-lac.

Shell-back. A well-seasoned mariner. An old salt.

Shell-fish. Mollusks or articulates, with a shell-covering, hard or soft.

Shelves. Dangerous shoals, shallows, or rocks, lying immediately under the surface.

Shelving. Gradually rising shoals or land.

Sheratan. The star β *Arietis.*

Shevo. A sailor-entertainment.

Shibah. A small Indian vessel.

Shield-ship. A ship fitted with heavy shields, to protect her guns. An improvement on the *cupola-ship*, it finally became the *turret-ship.*

Shield-tower (*Eng.*). A revolving turret.

Shieve. To row the wrong way. To assist the helmsman in a narrow channel.

Shift. A term applied to the disposing of the butts either in wood planking or iron plating, so that the greatest strength may be secured. A change in direction; as, a shift of wind. A party of men to relieve another party. To alter the position of anything. To replace one thing by another; as, to shift the ballast, to shift the berth, etc.

SHIFTER. An assistant to the ship's cook, who washed, steeped, and shifted the salt provisions.

SHIFTING-BACKSTAYS. Preventer backstays. See BACKSTAY.

SHIFTING-BALLAST. Pigs of iron, bags of sand, etc., used for ballast, and capable of being moved about.

SHIFTING-BOARDS. Wooden bulkheads in a ship's hold, used to separate the cargo.

SHIFTING-CENTRE. See META-CENTRE.

SHIFTING-SAND. Sand that changes its position by the action of tide or current.

Shimal. A severe northwest gale, accompanied by a cloudless sky, in the Persian Gulf.

Shiner. A light-house. The *dace*, a small fish.

Shingle. Coarse gravel or rounded stones.

SHINGLE-TRAMPER (*Eng.*). A coast-guardsman.

Shin Up. To climb up a rope or spar by the hands and legs alone.

Ship. The word ship (from Greek *skaptein*, to scoop out) is popularly used to designate any sea-going vessel larger than an undecked boat. But a ship, technically speaking, is a large vessel carrying from 11 to 12 square-sails on three masts, extended by yards, and also a number of jibs, stay-sails, and other square and fore-and-aft sails.

When we attempt to trace the history of the ship, we lose ourselves in a mass of traditions and conjectures. The early legends of most nations refer to the ship; but little knowledge of its origin and progress is to be gained from such allusions. First dwelling inland, and thence impelled by successive migrations to river, lake, and sea-shore, means of crossing these waters were devised. At first a floating log, then one hollowed out by fire or stone ax, answered the purpose; but larger sheets of water rendered necessary an assemblage of such trunks, and experience increased the buoyancy of such structures by adding a number of inflated skins to them. Others, where timber was scarce, prepared a wicker structure and covered it with bitumen or pitch, and thus crossed a rapid stream. From these primitive canoes (*monoxyles*), wicker-boats (*coracles*), or rafts (*schĕdai*, Gr.; *rates*, Lat.), gradually arose the first ship. Nor are we without legends as to these. Sanchoniathon, a Phœnician writer, informs us that Osoüs (a god) took a tree that a storm had thrown down and that lightning had hollowed out, and with it first ventured on the sea. He also says that Chrysor (*Vulcan*) designed the raft. Strabo ascribes the invention of the latter to Erythras, a king on the Persian Gulf. Isidore ascribes the invention of ships to the Lydians. The first voyage mentioned in the Bible is that of the sons of Noah, in Gen. vii. The ark, the first vessel there mentioned, was but a floating covered raft, 450 feet long, 75 feet broad, and 45 feet high, capable of bearing 15,000 tons. That some kind of vessel was designed before the final separation of the nations seems apparent from the fact that the Sanscrit and the Greek words (*naus*) ship are nearly identical.

The Chaldeans, the earliest historic nation, were doubtless navigators of the Persian Gulf, the Accad rulers being especially alluded to by Isaiah as "exulting in their ships." There originated the sea-god, who under the names of Dagon, Melkarte, Poseidon, and Neptune, endured for many centuries as the prime deity of the mariner. Thence emigrated the Phœnicians, carrying their sea-knowledge with them to the Mediterranean. The succeeding Assyrian, Median, and Persian states were non-maritime, and they and the Jewish kingdom had no influence in the development of the ship. When Sennacherib and Sargon conquered Phœnicia, the ships of that commercial state were used by them in further conquests, and by their aid Cypress was taken and Susa conquered. The earlier Assyrian sculptures show us only boats of reeds, and rafts of logs and inflated skins; but after these conquests, we see represented vessels with one or two banks of oars, evidently Phœnician, with sharp prow and high stern, or with equally high and curved stem and stern. Some of these were 40 feet long, and were rowed by from 18 to 22 men.

The Lydians, Carians, Cilicians, and other nations on the Asiatic sea-board, noted for their early piractical exploits, seem to have acquired their maritime knowledge from Phœnicia.

Egypt, whose monuments give us more exact notions as to her ships, was essentially a non-maritime state, although bordering on the sea. Her people detested and feared the sea, regarded salt water as defiling, and deemed it a disgrace to be buried in the sea. Mariners were of the lower caste, and only on the sacred Nile did they develop maritime knowledge. Monuments of 2800–2000 B.C. represent ships, and an inscription of King Una (2000 B.C.) mentions war-vessels, one assisting to tow boats laden with stone for the Pyramids. But until the advent of foreigners the Egyptians knew little of the sea, and it was only when Carians, Lybians, Phœnicians, and Cyprians brought them ships that they began to make conquests by sea.

The smaller boats used on the Nile were made of papyrus, and the larger, of short planks of acacia, overlapped at the edges, and calked with papyrus. Small vessels were propelled by poles, and larger ones by oars and sails, and the force of the current was utilized in coming down-stream. One of the oldest vessels shown on the monuments has 40 oars, and is probably 100 feet long. It had a double mast made of two spars, and a large square-sail bent to a yard, and managed by sheets and braces. Later, vessels are shown, both war and merchant, with one mast and one square-sail, spread between two yards revolving about the mast in a kind of boxing Rameses II. had a large fleet of war-galleys, and is said to have equipped 300 ships on the Red Sea. Vessels were highly ornamented, the lotus and sacred animals being painted on oar, rudder, prow, and stern, and the sails were sometimes embroidered and ornamented in colors. King Pepi, of the 6th dynasty, is said to have sent the first expedition beyond the mouth of the Nile.

But the great maritime people of antiquity were the Phœnicians, whose ships monopolized the entire trade of the Mediterranean for many centuries, and whose merchant fleets sailed from the Syrian Sea into the Ægean, the Euxine, and Tyrrhenian Seas, and to the Western Mediterranean, and established colonies that perpetuated their maritime renown. They furnished the models for war and merchant vessels to all the surrounding nations, the *Gauli*, or round ships, and the *Arco*, or long ship (query, *Ark? Argo?*), distinguishing the classes. We know from Assyrian sculptures that they invented the bireme, with 2 ranks of oars, and Clement of Alexandria says they first planned the trireme, with 3 ranks, imparting the knowledge to the Corinthians, usually credited with its invention. Greek ships were closely modeled from Phœnician, and it was the misfortune of this unwarlike and commercial people to be a frequent conquest of other and more mighty powers. Thus they furnished fleets to Egypt, Assyria, Persia, and Judea.

The earliest beginnings of the Greeks are connected with navigation and ships. Such beginnings extend back into the heroic ages, and can only be traced in the numerous myths and legends handed down through various sources. So the stories of the advent of Danaus, Cecrops, Inachus, and others, doubtless involve voyages of settlement and discovery, while the legends of Pegasus, Phryxus, Perseus, Icarus, and the Rapes of Europa and Io refer to the first appearance of the ship. Dardanus is said to have come to Troy, after the flood, in a leather-covered boat. The Homeric vessels at the siege of Troy were small undecked boats, carrying from 50 to 120 men, hauled up on shore when not in use, and even carried when necessary. The first long voyage of Greek ships is typified in the story of the Argo. Long before the western Greeks were interested in the revival of navigation, those of the Asiatic towns and the islands were hardy and skillful navigators, and planted many maritime colonies. Minos of Crete first subdued the Carian and Cilician pirates, and is said to have possessed the first marine. The larger islands, Samos, Chios, Lesbos, followed after Crete, and as the Corcyran, Corinthian, and Athenian states became interested in maritime affairs, the ship was perfected more and more, the war-vessel particularly improved, and the Greeks gradually succeeded the Phœnicians as masters of the Eastern Sea. When the great conqueror established the Macedonian empire, a new impulse was given to navigation, and the Indian Ocean, hitherto unknown to the Greek mariners, was soon regularly traversed by their keels. The Ptolemies were especial patrons of the maritime arts, and the foundation of Alexandria favored them in advancing trade and commerce.

The Carthaginians followed in the wake of their illustrious predecessors, the Phœnicians. Commerce was their aim, as it had been that of their ancestors, but instead of succumbing to the attacks of their enemy, they resolutely contended against the power of Rome, developing the war-ship in the course of the struggle in which they finally perished. They are said to have first built the quadrireme and the quinquereme, with their 4 and 5 ranks of oars. They extended farther the navigation of their predecessors, sailing beyond the pillars of Hercules, as far as the Scilly Islands north, and Cape Bon south, and even, if we rightly interpret the tradition, circumnavigated Africa.

Their enemies, the Romans, at first ignorant of nautical matters, copied their ships and launched huge fleets in incredible spaces of time. They designed new means of contending against their enemies and developed the war-vessel to some extent. The various Greek colonies in Italy and Sicily aided in developing the ship, and the Phoçæan colony of Marseilles has not yet lost the prestige early gained in maritime affairs.

The Arabians and Indians are said to have possessed ships and to have navigated the waters nearest them at an early date, but we know little of them. The Parthians and most barbarians known to the Romans were non-maritime peoples, and only a few possessed boats of leather or canvas. Nor do we know any reliable facts as to the great antiquity claimed by the Chinese to maritime skill and invention.

Having thus brought the history of the ship down to mediæval times, we will glance briefly at the ancient ship, as given to us in the writings of the Greeks and Romans.

Ancient ships were divided into two great classes,—the war-ship or long ship (*neēs makrai*, Gr.; *navis longa*, Lat.); and the merchant or round ship (*stroggulē*, Gr.; *navis onerariæ*, Lat.). The Greeks called the real fighting-ships *Tacheiai*, the transports, *Stratiōdēs*, for men, and *Hippagōgēs*, for horses.

The long ships were row-galleys seven or eight times as long as broad. No question has been more unsatisfactorily discussed than that of the arrangement of the oars in these galleys. At first, they seem to have been designated by the number of rowers, as *Eisosoroi*, singly rowed, *Triacontoroi*, 30-oared, *Pentekontoroi*, 50-oared, *Exakontoroi*, 60-oared, and others, all classed as *Monokrotos*, or with one rank of oars. But later, vessels with more rows of oars were planned (*Polykrotos*), and we find the *Diereis*, or *Biremis*, the *Trieris*, or *Trireme*, the *Tetreis*, or *Quadrireme*, the *Pentereis*, or *Quinquereme*, the *Hexereis*, or *Sexireme*, the *Heptereis*, the *Oktoreis*, the *Dekereis*, or *Decireme*, carrying respectively 2, 3, 4, 5, 6, 7, 8, and 10 ranks of oars, and we even hear of the *Ekkaidekereis*, *Pentekondekereis*, and *Tessakontereis*, of 15, 16, and 25 banks of oars. Some authorities now believe that in the case of galleys above 5 ranks of oars, the perpendicular groups are understood to be numbered, and not the horizontal rows. The *Hexereis* and *Heptereis* are said to have been invented by Dionysius II., tyrant of Syracuse.

The men rowed the oars seated on benches, one to an oar. The oars were 4 feet apart, those of each row 1 foot in advance of that below, and 2 feet above it. The lower rank of rowers were called *Thalamitai*, the next *Zugitai*, the third *Thranitai*, the fourth *Tetreritai*, and the fifth *Penteritai*. The oars were 7½, 10½, 13½, 16½, and 19½ feet long, and the third row was 5½ feet above the water, the fifth 8 feet. The shape of the galley in section was like a V, expanded at the top. Ships were built with keels, ribs, beams, stem and stern-post as now. At first, only a partial deck extended along the sides, serving as a deck for the *Epibatai*, or fighting men, but these are said to have been joined in a deck by Cimon at the battle of the Eurymedon. The stem rose in a curved ornament, shaped like a gooseneck turned back (*Cheniscus*), and over the stern was a leaf-shaped shelter, the *Aplustre*.

One mast, with a square-sail set on a yard, was used, and sometimes two. Triremes were generally used by the Greeks, and quadriremes and quinqueremes by the Romans. The trireme usually had a crew of 200 rowers and 30 marines. At or near the water-line, sharp prows were added to serve as rams, three or more being sometimes seen. The Romans added square towers to the decks of their ships, and employed military engines on their decks. About the time of the battle of Actium (30 B.C.) the *Liburnian galleys* came into use. We know little of them, except that they were light and handy,—a reaction against the ponderous, many-oared galleys then in use.

Besides being shorter proportionately, the merchant ships were shaped alike at bow and stern. They were sometimes large, able to carry from 200 to 800 passengers. They used 3 masts, the sails on the middle one being the largest, and there being sometimes 3 on that mast. The Romans used in some vessels triangular topsails, called *Suppara* (*shift*). Many sailing-ships made good passages, vying with our modern sailing-vessels, and the galleys made, on occasions, still better speed, 8 to 9 knots not being uncommon. The rudder was always a paddle over the stern, there generally being two, one on each side.

During the Middle Ages the modern ship had its rise. At first the progress of improvement was slow. Upon extinguishing ancient civilization, the Northern barbarians were at first unmindful of the necessity of a naval force to the peoples living on the border of the great sea, and neglected maritime affairs. The Vandals, however, found that the aid of a fleet was necessary to the conquest of the African provinces, and Genseric availed himself of the skill of others to create one. The boats used on the Black Sea were but frail ones, and the lower Latin empire did little toward developing the ship. The Arabians, or Saracens, after overrunning Africa and Spain, engaged in building large ships, but they were somewhat unwieldy and cumbrous. The Rhodian power was prominent early in maritime affairs, and gave the first code of maritime laws to the world. The northern nations of Europe appear early in the Middle Ages as daring seamen, pirates, and fishermen, and their early legends repeat the many heroic deeds of the vikings and their contemporaries. They were the first to undertake long voyages out of sight of land, and first crossed the Atlantic, a terror to the mariner of the Mediterranean. They gave a powerful impulse to the development and improvement of the sailing-ship. The Saxons, after acquiring England, neglected marine affairs until the advent of the piratical Danes led Alfred to found a naval force to repel their incursions. Toward the middle of the period we are considering, the gradual rise of the nations of Europe, the founding and growth of the Norman, Venetian, Genoese, and Catalan states gave a remarkable impulse to maritime affairs. Ships increased in number, variety, and types, and while merchant fleets covered the Mediterranean, the jealousy of these maritime powers developed great fleets of formidable row-galleys. The Crusades aided materially in the development of navigation, by leading English, French, and Flemish powers to send ships on longer voyages, and acquainting them with Medi-

terranean ships. Then followed the introduction of the mariner's compass, the invention of ordnance, and of maps and instrúments of navigation, all directly affecting the ship and rendering possible the great discoveries of the next century, with which, undertaken by Portuguese, Spanish, and English, we close the Middle Ages, with the ship proper fully developed into a strong and stable structure, able to buffet the waves of the Atlantic, and to undertake greater triumphs in the future.

The vessels of the Middle Ages, infinite in variety of class and size, are all referable to one of three classes, viz.: 1. The row-galley, comprising many types, the chief of which were the pinaza, galiot, gatte, saette, fuste, brigantine, dromon, galardella, galea, galea bastarda, galea grossa, galeide, galeasse, chelande, ramberge, pamphyle, and demi-galère, and in the North, the esneke, drakar, and jarnbaud. 2. The sailing-ship, navis, naos, nef, or navire. This comprised a very numerous class, among which we find the nao, balaena, carabella or caravelle, tartane, coca or cog, galleon, zelander, huissier, buzo or buss, gumbari, carracca or carrack, taride, grip, heu, hokebot, aak, flibot, barca or bark, barkane, bardetta, brigantina or bergantin, caravellone, caramoussal, frégate, frégatone, maone, marsillane, and palandra. 3. A mixed class, including the selandra-pamphyle, zelandra-huissia, buzo-navis, and others. These vessels differed *inter se* as to form, size, sail-rig, number, and arrangement of oars, etc.

First, then, as to galleys. These vessels resembled each other greatly. As in ancient times, they were long, narrow, and low-built vessels, principally propelled by oars. But they differed from those of antiquity in having seldom more than one row of oars. These oars were sometimes arranged as in the modern boat, with one man to an oar. The number of banks on each side varied from 8 to 36, with sometimes a bank less on the port side, to make room for the cooking-place. Other galleys had 2, 3, 4, 5, 6, and 7 men to an oar, thus increasing the power without lengthening the galley. Three were more common in the 14th century, and 4 in the 16th, in the light, or *subtile* galley. The bastard galleys, or larger ones, increased this to 5 and 6 men to the oar, and the chief galley, or capitana, and King's galley, or reale, usually had 6 to an oar. Seven to an oar was rarely found, but galleys with 5 to the former half and 6 to the after half, or some such arrangement, were not uncommon.

Nor was this the only way of arranging the oars. We also find galleys with more than one oar to a bank, two or more coming through the same port, and each being managed by one man. Two oars to a bank was a common arrangement in the 14th century, while we find 3 in the 15th, and 4 and 5 in the 16th centuries. There is also mention of a galley with 7 oars to a bank, but it was not successful.

These galleys, then, either rowed *à sencille*, that is, with one man to an oar, or *di scaloccio*, that is, with many men to the same oar, had for a crew from 100 to 250 men. These were in later times slaves or convicts, and were chained to the banks night and day, protected from the sun only by an awning, and exposed to the water coming in the low row-ports. The banks were, with one oar to a bank, perpendicular to the keel, but when many oars were rowed from the same bank, it was at an oblique angle to the keel. The forecastle and poop were sometimes decked over, sometimes occupied by houses or cabins, and were connected by a central gangway, on which the mates promenaded, applying whip and voice to quicken the labors at the oar. After the introduction of artillery, the guns were at first only mounted to fire ahead, under a parapet or *rambade*, then a few were placed between the oars in broadside.

Two masts with square-, lug-, or lateen-sails, and occasionally a third small mast, furnished the auxiliary sail-power to the galley.

The forward or, in case of three, the middle mast carried the largest sail. Upper sails were seldom used on the galleys.

A galley with 25 oars to a side was 125 feet long, 16 wide, in the 14th century, while the French galley, a century later, was 150 feet long, 30 wide. The hold of the galley was divided into store-rooms, cabins, etc., and a *tavern*, where wine was sold to the slaves.

The galiot, pinaza, saette, fuste, ramberge, frégate, frégatone, galea, galeardella, galeide, demi-galère, and brigantine were smaller than the galley, as were the row-galleys of the Northern nations. The taride, the galea grossa, the pamphyle, chelande, dromon, and galeasse were large galleys. Besides these, there were many others of this class, but these are the principal ones.

The speed of the galleys when under full way was considerable, and 9 or 10 knots were not uncommonly attained.

The galley was a shallow vessel, and its walls were prolonged by knees, forming projecting supports for the oars and for the stanchions supporting the awning.

An equally great variety of sailing-vessels meets us in the Middle Ages. The sailing-ship was called navis, nave, or nef, with diminutives of these words. These vessels differed greatly in size, and increased generally toward the end of the period. These were ships of one, two, and three decks, and of various dimensions, but their general characteristics were the same, they being short, round vessels, built for carrying and not for speed, and with bow and stern alike in some cases, but not always. Their sail-rig was equally varied. One, two, three, and four masts were used, and one, two, and three sails on those masts, in form lateen, lug, square, or trapezoidal. These ships were, toward the end of the 13th century, from 1000 to 1500 tons burden, carrying, some of them, from 500 to 1000 passengers. The ships of the Normans were smaller, and those used in the invasions of France and England were but large open boats with one sail on a single mast, and this rig of one square-sail on one mast was a common one in the smaller vessels of the 11th to the 13th centuries. The nefs were short and round, with bluff bows and square sterns, and forecastle and poop began to rise in height in the 15th century. Lateen-sails, used at first on the larger ships, were gradually replaced by square-sails, except in the case of main and mizzen, which remained lateen-sails. At first paddles were used to steer by, but the rudder came into use in the 14th century, and was soon universal. The galion was longer and

finer than the nef, and became the largest of the class, equaled by the carrick, a high, broad, unwieldy vessel, of some 150 to 165 feet long, and from 40 to 47 broad, and carrying upwards of 1000 tons burden. The marsillane was a large, square-sterned vessel; the hokebot a short, round Dutch fishing-boat. Maones were large and unwieldy Turkish vessels. Tarides were large transports, and uissiers were horse transports, capable of carrying 40 horses. The caramoussal was another large, unwieldy Turkish vessel, and palandries were Turkish transports. Caravelles were small lateen-rigged vessels, from 50 to 150 tons burden. Columbus made his voyages in such vessels, which were fast, handy, and easily managed, and were much used in the 15th and 16th centuries. Buches were also large vessels, baleiniers short, high-pooped fishing-vessels, and gumbaries large sailing war-vessels. Tartanes were moderate-sized, and the zelandre was a sailing-vessel of 90 to 100 tons in the 13th century.

The grip, heu, aak, and flibot were small coasting-vessels, and the bark was a small vessel with two masts, having single sails on each. Its diminutive, the barchetta, and its augmentative, the barkasse, resembled it in form and appearance. The brigantine was a small, rapid vessel, much in favor among pirates.

The frégate of the Middle Ages was a small lateen-rigged vessel with one mast and undecked, and the frégatone a larger vessel of the same class.

The vessels of the third class resembled both the galley and the nef, partaking of the rig of one and the characteristics of the other. These were not numerous, and merit no particular description.

We are thus brought down to the 16th century. We have seen larger and more seaworthy vessels resulting from the commercial rivalry of the Italian states and the establishment of modern naval powers, and we may thus commence the modern epoch with ships fitted to make those great voyages of discovery which soon followed.

The conquest of Constantinople by the Turks had checked maritime development, and the decay of the Italian maritime states had an equally depressing effect. But the rise of more lasting powers on the Atlantic coasts, and their voyages for gain and discoveries, gave an impulse to the improvement of the ship, while the contests for supremacy on the ocean in which they became involved, also improved and enlarged the war-vessel. Spain and Portugal at first, then England, France, and Holland, were noted for superior and improved vessels, as their successive discoveries led them to make regular voyages. The formation and development of trading companies had their share in the nautical march of improvement. The permanent navies established by these nations to defend their merchant fleets soon grew in size, and improved the qualities of their ships. War-galleys, hitherto relied upon in the tranquil Mediterranean, would no longer do for the more stormy Atlantic, and the sailing ship of war had then its real rise and development. To the clumsily-shaped hull succeeded scientifically-constructed models of great beauty. To the lateen-sail succeeded the square-sail, and this, in turn, was partially displaced by the trapezoidal sail in small vessels. With the revival of science, the principles affecting the form and conduct of the ship were established, and scientific construction gave better vessels and greater speed. Investigations into the effects and properties of waves, of the wind on the sails, of means of preserving wood, and the ship's bottom, further benefited the construction of the ship. Artillery increased in size and power, and the warship became larger and of stronger build, until, in the 18th century, the ship of the line of 110 to 120 guns reached the highest development of the fighting-ship of the sail period. The high and unwieldy poop and prow at first were cut down, then a century later the square stern, loaded with sculpture and ornaments, was abolished, and the ship more nearly approached its present form and more useful proportions.

The use of iron, first as an aid in building spars, then for the frame, and finally for the rigging and spars of the ship, gave greater solidity and lightness. Iron was first proposed for frames in 1809, and the first iron ship was built in 1818, the "Vulcan," on the Clyde River. But the first sea-going iron vessel was the "Elburkah," of 55 tons. Improvements in sail-rig followed. Double topsail yards, giving greater command of the sails with fewer men, were invented by Mr. Forbes in 1845. Other improvements in the form, construction, and conduct of the sailing-vessel were made, until the clipper, the most perfect sailing-vessel of all ages, was designed, and speed increased from 8, 9, and 10 knots to 15 and 18.

Before tracing further the history of the ship, we must go back to the first beginning of a new power in propelling ships. Sailing-vessels, with all the improvements, were yet dependent on wind and tide; but steam came to the aid of the mariner when most needed, in the increased commercial intercourse of modern times, and rendered him independent of adverse winds or tides.

This is not the place to trace the steps that led to the final construction of the steam-engine. From Blasco de Garay in 1543, to Fulton in 1793–1800, these experiments and preliminary steps were made, finally resulting in the marine engine. The first successful application of steam to move a vessel was that of Fitch, in 1786; and Fulton, in 1809, built the "Clermont," the first regular steamer to ply on rivers. Bell, in 1811, built the "Comet," the first steamer in England. The screw-propeller was the next improvement. It was first applied to steam-vessels in 1836, the "F. B. Ogden," built by Ericcson, being the first screw-vessel. The first steam man-of-war was the "Comet," built in 1819, in England; and the "Princeton," built in 1841, was the first screw man-of-war. The first line of steam-vessels was established in 1822, in English waters. The "Savannah," in 1819, first crossed the ocean by the aid of steam, but a transatlantic line was only established in 1838. The first of the present great lines was the Cunard, in 1840. Up to this time the average speed obtained was from 7½ to 9 knots, and the greatest 11 knots, per hour. Other lines were soon established, and regular communication by steam is now maintained all over the world. As steamers thus came into use, it was found that wood was still less fit for their frames and hulls, and iron rapidly replaced it. Steamers

grew rapidly in size, the first being 40 to 60 tons, until on the establishment of the transatlantic lines they had risen to 1200 and even 2000. The short and broad hull of the sailing-vessel was lengthened, and the lines of the steamer became longer and finer, until it attained the proportions of the old row-galleys. The sailing-vessel had been in length from 4 to 5 times the breadth, and now the steamer reached 9 and 10 times its breadth. The "Great Britain," built in 1843, reached a great size, being 322 feet long and 50 broad, and carrying 2984 tons, with engines of 1000 horse-power. But considerable sail-power was still retained in her 6 masts, 2 of them square-rigged. This increase in size culminated in the "Great Eastern," launched in 1858. This enormous structure was a double keelless iron vessel, with several compartments, separated by water-tight bulk-heads. She is 692 feet long and 85 broad, with a total tonnage of 22,500, and was intended to accommodate 4000 passengers, or 10,000 soldiers. One hundred and ten furnaces, under 10 boilers, supplied the motive-power to the 4 paddle- and 4 screw-engines, besides furnishing steam to the 6 smaller engines of 300 to 400 horse-power. These engines of 2600 nominal, or 11,000 actual horse-power, are able to move the enormous hull at the rate of 14 miles an hour. Twenty large boats are carried on davits, and 2 steamers 100 feet long may be carried on the guards. She also had 6 masts, the second, third, and fourth only being square-rigged. But her great draft (30 feet), and the cost of running her, has made her unprofitable as a passenger steamer, and her principal use has been to lay telegraph-cables, for which her great size and steadiness fit her.

The most successful vessels of the great ocean lines, although they fall far short of this monster, are still of great size. The "City of Berlin" of 5000 tons, the "Sardinian" of 4200, the "Scythia" of 4557, and the "Iberia" of 4761, are among the largest. An average of 3000 tons is not uncommon. Many of these steamers have 4 masts, others 3, but sail is always auxiliary, steam being the chief reliance. Enormous fleets of these steamers are now possessed by the great steam lines of the world. In 1875 the Cunard line had 49 vessels of 90,000 tons and 14,500 horse-power; the Inman line, 16 of 44,000 tons and 7000 horse-power; the Allen line, 20 of 54,000 tons and 8000 horse-power; the Anchor line, 30 of 70,000 tons and 15,000 horse-power; the Royal Mail, 23 of 51,000 tons and 9300 horse power; the Pacific Company, 54 of 119,800 tons and 21,395 horse-power; the Liverpool and River Plate Company, 30 of 32,995 horse-power; the Peninsular and Oriental Company, 50 steamers of 122,030 tons and 22,000 horse-power; and the Messageries Maritimes of France, the largest number of all, 66 steamers of 175,000 tons.

Since the adoption of iron for the frames and hulls of steamers, the growth of these vessels has been very rapid. In 1861 there were 159 iron vessels of 68,560 tons built in England, the chief mart of this trade; and in 1867, 224 of 90,823 tons; in 1872, 446 of 335,750 tons. In all, in 13 years, there were built there 4185 steamers of 2,489,840 tons.

While iron ships increased, steam-vessels also replaced sailing-ships rapidly. The decrease of sailing-vessels from 1870 to 1873 was 5.44 per cent. in numbers, or 11.57 per cent. in tonnage; also 6.67 per cent. in size. On the contrary, steamers increased in number 54.9 per cent., in tonnage 24.59 per cent., and in size 6.67 per cent. In 1876 there were 5771 steamers of 5,506,842 tons, and 58,208 sailing-vessels of 15,553,338 tons. Steel has also been used to some extent in building ships. There were some built as early as 1860; but only 3 were built from 1866 to 1876, and one in 1878. That year 574,819 tons of shipping were built in England, of which 52,657 was of wood, 517,692 of iron, and 4470 of steel; or 9 per cent. of wood, 3.4 per cent. of steel, and 87.6 per cent. of iron. A steel ship is now building for the White Star line, which is to be 546 feet long, 50 feet beam, and more than 8500 tons in burden.

But when we come to look at the modern man-of-war, we find more remarkable changes during the modern period. At the beginning of the 16th century, the row-galley was still the main reliance in the fleets of European powers. But as we have seen, it was already being replaced by the sailing war-vessel. As this took place the vessels increased in size, improved in sail-rig and in construction, and the enormous structures on poop and forecastle were leveled to the deck. Ports, usually ascribed to Descharges, of Brest, were invented before his time, and guns were mounted in broadside in the sailing-vessel.

The fleets of sailing-ships that during the 17th and 18th centuries contended for supremacy were principally made up of those lofty three-deckers, —short, high, and unwieldy, but formidable from the number of guns they carried, and necessarily opposed to them were ships of the same class. This supremacy of the ship of the line was weakened by the introduction of the steam-vessel and by the construction of heavier frigates. This, the next vessel in size, gradually attained a greater importance as its dimensions increased. So long as the paddle-wheel was in use, steamers were not of great size, but the introduction of the propeller again brought vessels of the line into use; but their importance as a fighting-vessel had ceased, and comparatively few steam-liners were built. With the introduction of the screw the sailing man-of-war was doomed, and steam-vessels thenceforth took the first rank in all navies. Wood is still used for unarmored vessels, but is being replaced by iron, and armored ships are built of iron or steel. The latter material is taking a decided place in war-ship construction. Eight unarmored corvettes are building for the English navy, and steel has been used in the construction of some recent armored vessels. The advent of the armored ship has totally changed the types of vessels for war, and all unarmored vessels are now only adjuncts to the more powerful protected ships. The introduction of armor has caused extensive changes in construction to meet the demands for greater strength and rigidity, and the latest men-of-war differ totally from those of fifty years ago. Better engines, with greater power, have also resulted from the construction of such heavy and ponderous vessels. The unarmored steam-vessel has gradually increased in size, until sloops exceed in size the line-of-battle ships of the 18th century, and armored ships have gradually increased

in size also. In the middle of the 16th century, the "Henry Grace à Dieu," regarded as unusually large, was no more than 1000 tons, although her high poop and forecastle gave her the appearance of greater size. A century later we find the great "Royal Sovereign," the largest man-of-war then built, and the first English three-decker, to be 232 feet long by 50 wide, and only 1861 tons burden.

Still a century later, and the "Royal George," of melancholy fate, the greatest ship of her time, was only 190 feet on the middle deck, 52 feet broad, and 2280 tons burden. But at the end of this 18th century we find the Spanish "San José" to have increased to 2457 tons, being 194 feet on the middle deck, by 54 beam, and carrying 112 guns, while the English "Caledonia," the largest of the old wooden liners, was 205 feet long, 54 beam, and 2616 tons burden, with 120 guns. Not the less remarkable is the increase in size of steam war-vessels. The first, the "Comet," was 238 tons, and of 80 horse-power. This was in 1822, and five years later the "Carron" measured 494 tons, and her engines were 120 horse-power. In 1830, the "Medea," of 835 tons and 220 horse-power, was in use, and in 1839, these dimensions had increased to 1195 tons in the "Cyclops," of 320 horse-power. In 1843, the "Albert and Victoria" yacht measured 1442 tons, with engines of 400 horse-power, and in 1845 the "Terrible," of 1850 tons and 800 horse-power, was built. In 1846, the "Dauntless," of 2432 tons, was 218 feet long and 39 beam. Iron ships then carried further this increase in size. The French built seven 120-gun ships in 1845 which were over 5000 tons displacement, and in dimensions 210 feet by 51. Armored ships checked this development at first, then carried it to greater lengths. We find the "Warrior," the first English ironclad, to be 380 feet long, 58 beam, and of 9681 tons displacement, and the "Northumberland," in 1865, increased this to 10,395 tons, and to 400 feet in length and 59 in breadth of beam. The "Dreadnaught," in 1875, further carried these dimensions to 10,866 tons, but shortened the length to 320 feet, with a beam of 63 feet, and, finally, the "Inflexible" reached 11,520 tons displacement, and with the same length as the "Dreadnaught," increased the breadth to 75 feet. The probable limit in size of armored vessels is reached in the "Italia" and "Lepanto," which are 13,400 tons in displacement, 400 feet long and 74 beam. The noticeable feature in the development of size in steam war-vessels has been the gradual increase of length from a proportion of 5 to 1 of breadth, until 7 and 8 to 1 were reached, and then, as weight of armor increased, these proportions came down, until the "Inflexible" presents a proportion of 4.2 to 1. Modern construction has also brought the weight of the hull down to a minimum of 39 per cent. of the whole weight for iron hulls, and 34 per cent. for steel hulls, from an average of 46 per cent. in the wooden hull. Sail-rig has altered little in the man-of-war, but the gradual adoption of steam as the principal motor has led to a rejection of much of the rig of the sailing-vessel, the lighter sails being dispensed with in steamers, and sail-power entirely discarded in certain classes of heavy armored vessels.

While the types of modern ships are perhaps as numerous as at any time in the history of the ship, they are more easily classified by an artificial system, many of which have been in use. These have reference: 1. To the number of guns. 2. To the tonnage. 3. To the rig of the vessel. 4. As regards the condition of the hull. 5. As to the mode of arranging the defensive armor and battery.

During the 16th and 17th centuries the mode of classifying war-vessels by the number of guns they carried was in common use. We have thus, ships of 120, 112, 100, 98, 86, 82, 80, 74, 64, 60, 56, 50, 44, 40, 38, 36, 32, 28, 24, 22, 20, 18, 16, 14, 12, 10, 8, 6, and 4 guns. These ships were also classed from the number of decks on which guns were carried, as ships of the line (double-deckers and three-deckers), frigates, sloops, pinnaces, etc. As to a classification by tonnage, we find such in use in the Spanish Armada; merchant ships are so classed, and tonnage, or displacement, is made the basis of a classification for modern naval vessels. See CLASSIFICATION.

All ships are classed according to rig, and a description of these vessels will be found under the head of sloop, frigate, bark, barkantine, brig, brigantine, schooner, cutter, polacre, xebec, etc. Modern men-of-war are classed by rates, according to the tonnage, and are also vaguely referred to from the manner of their armament or the arrangement of their armor. A proposed division of these vessels as given below is from the Austrian work "Die Marine," by Von Littrow, with additions. Ships are, by this, classed:

1. By size and draft.
    - A. Sea-going.
    - B. Coasting-vessels.
2. By the materials and system of construction.
    - A. Wooden vessels.
        - *a.* Transverse frames.
        - *b.* Diagonal built.
    - B. Iron vessels.
        - *a.* Transverse frames.
        - *b.* Longitudinal frames.
        - *c.* Bracket frames.
    - C. Iron vessels cased with wood.
    - D. Composite vessels (iron frames and wood planking).
    - E. Steel vessels.
3. According to defensive power.
    - A. Unarmored.
    - B. Armored.
4. According to propelling motor.
    - A. Sailing-vessels.
        - *a.* Ship.
        - *b.* Bark. { 1. Bark. 2. Barkantine.
        - *c.* Brig. { 1. Brig. 2. Brigantine. 3. Hermaphrodite brig.
        - *d.* Three-masted schooner.
        - *e.* Schooner. { 1. True schooner. 2. Topsail schooner.
    - B. Steam-vessels.
        - *a.* Paddle-wheel.
        - *b.* Screw-steamer. { 1. With 1 screw. 2. With 2 screws. 3. With 4 or 6 screws.
        - *c.* Hydraulic reaction ship.
5. According to the destination of the vessel.

- A. Ships of the line.
  - *a.* For home waters.
  - *b.* Sea-going.
  - *c.* Station vessel.
- B. Cruisers.
  - *a.* To capture other cruisers.
  - *b.* To capture mail-steamers.
  - *c.* For cruising and dispatch purposes.
  - *d.* Station gunboats.
- C. Coast defense ships.
  - *a.* Offensive.
  - *b.* Defensive.
- D. Dispatch-vessels.
- E. Transports.
  - *a.* For troops.
  - *b.* For material.
- F. School-ships.
  - *a.* Sea-going.
  - *b.* Not sea-going.
- G. Torpedo ships.
- H. Harbor vessels,—tenders, tugs, pilot-vessels, guard-ships, coal-hulks, powder-hulks, store-hulks, etc.

6. According to the arrangement of guns or of defensive means
   - A. Rigged vessels.
     1. With full battery.
        - *a.* Guns on spar-deck (flush-deck corvette and gunboat).
        - *b.* Guns on 1 covered deck (decked corvette).
        - *c.* Guns on 2 decks (frigates).
        - *d.* Three tiers of guns, 2 covered (two-decker).
        - *e.* Four tiers of guns, 3 covered (three-decker).
     2. With central battery.
        - *a.* Without bow and stern fire.
        - *b.* With 2 chase-guns.
        - *c.* With 3 chase-guns.
        - *d.* With 4 chase-guns.
     3. With turrets.
        - *a.* Fixed.
        - *b.* Movable.
   - B. Mastless ironclads.
     1. Without a central redoubt (monitors).
        - *a.* Single turret.
        - *b.* Double turret.
        - *c.* 3 or 4 turrets.
     2. With central redoubt (breastwork monitor).
        - *a.* With 1 turret.
        - *b.* With 2 turrets.
          1. In line of keel.
          2. Diagonally placed.
   - C. Circular ships.
     - *a.* Popoffkas.
     - *b.* Livadia style.
   - D. With guns *en barbette.*

Under some one of these classes comes each man-of-war, armored or unarmored, steam and sail, and all merchant vessels.

In the matter of speed great progress has been made. As many as 17 knots and even 18 has been attained by the larger ships among the men-of-war, and from 23 to 25 miles an hour has been made by merchant steamers, while the smaller torpedo-boats attain this great speed, and are expected to surpass it. The modern man-of-war is a mass of machinery, and reliance is wholly placed upon the engines in case of a battle, as was anciently placed in the oar-power. The limit as to size has been attained, both in men-of-war and merchantmen, and much greater speed cannot be expected, while the gun has triumphed over the armor, so that development in that direction seems checked.—*F. S. Bassett, Lieutenant U.S.N.*

Shipboard. *On shipboard*, on board a ship.

Ship-breaker. One who breaks old ships in pieces when no longer fit for use.

Ship-broker. A mercantile agent who transacts business for ship-owners and merchants, buying and selling ships, procuring cargoes, etc.

Ship-builder. A shipwright; one who builds ships.

Ship-building, Iron. By the substitution of iron for wood as ship-building material the general theory of naval architecture, including the computations of weights, displacement, centres of gravity, meta-centres and stabilities, strains to which the structure is subjected, speed, etc., is not essentially modified; but in the mechanical execution a radical change is effected, the art of the wood-worker yielding its prominence to that of the iron-worker. The saw-mill, broad-ax, adz, auger, and treenail are nearly superseded by the furnace, the rolls, the iron-shearing or planing-machine, the drill, punch, and rivet. The labor of the draughtsman, particularly in such matters as the geometrical constructions for joining necessarily short pieces like timbers, is materially diminished; but extreme accuracy is required in laying off the mold and beveling templates of every frame, as there can be no fairing of the body, as by dubbing with an adz in wooden ships, after the structure is placed in position. As iron can be hammered, bent, twisted, riveted, or welded into any conceivable form, and so arranged as to utilize its utmost resistance to all the varied strains to which a ship is subjected, it is eminently adapted to such structures. Experience has amply demonstrated their superiority, both in strength and durability, over wooden ships; also that the latter are incapable of sustaining the steam-power required at the present day. Of the many notable proofs of the strength of iron ships two may be cited, viz., the grounding of the "Great Eastern" in Long Island Sound a few years since, and the recent collision of the Guion steamship "Arizona" with an iceberg in mid-ocean while running at a speed of 15 knots an hour. The former vessel was extricated, after replacing a few plates, without strain to her general structure, the latter continued her voyage after a short delay.

There are three general methods of framing iron ships, viz., the *transverse system*, the *longitudinal system*, and the *bracket system*, which is a combination of the other two. The *solid floor system*, as applied to unarmored vessels of war, is also a combination of the two first mentioned, and in a few instances *diagonal framing* has been attempted, but did not meet with favor.

In the simplest form of framing, which is the *transverse system*, the frames are arranged transversely across the keel in the manner of those of wooden ships. The frame is composed of three parts, viz., the *frame angle-iron*, or outer angle-iron, to which the outer plates are riveted; the *reverse frame*, or inner angle-iron, to which

the ceiling, etc., is fastened, which is curved in a contrary direction and riveted to the frame angle-iron side to side from the top sides to about the turn of the bilge where it begins to diverge, being sufficiently separated at the keel, where it ceases, to give proper depth to the floor; and the *floor-plate*, which extends from the turn of the bilge on one side of the ship to the same point on the other, and to which the flanges of the frame and reverse frame are riveted. When the keel is continuous the floor-plates are in two pieces, but when the floor-plates are in one piece the keel is worked intercostally. The simplest form of keel is a plain bar, of which the *stem-post* and *stern-post* are virtually continuations, the *garboard-strake* being flanged and riveted thereto. The *deck-beams* are commonly of T bulb-iron, the ends being fashioned into arms and riveted to the frames. The *decks* are of wood, but under the planking on either side of the hatches, and riveted to the tops of the beams, are heavy plates of variable width called *stringers*, extending the whole length of the ship. The stringers, together with the *water-ways* and top plating, give most of the strength to the upper chord of the structure. *Side-keelsons*, the chief source of longitudinal strength of the lower portion of transverse framing, are usually worked intercostally, but sometimes altogether inside the reverse frames. The outside plating is *butted* at the ends and *lapped* longitudinally below the water-line; but above the water-line the sides may be made smooth by butting the longitudinal seams also. *Frames* are bent to the mold, after heating them in a reverberatory furnace, upon a large cast-iron plate perforated with square holes, called a *bending slab*.

In the *longitudinal system*, the frames are disposed fore-and-aft the vessel, and are thus better adapted to withstand longitudinal strain, which in long ships is exceptionally severe. The ship is divided by several transverse bulk-heads, and these frames or stringers are so arranged from bulk-head to bulk-head that one passes along the center of every plate of the skin, giving to each strake of plates the continuous strength of an iron beam. Between the bulk-heads the frames are supported by partial bulk-heads, or continuous iron rim, forming a girder running transversely all around the ship. The inner skin, for a great portion of the length of the hull, may be made of plates and calked, thus giving great additional strength, and insuring the vessel against leakage in case of accident to the outer plates.

The *bracket system*, or combination of the transverse and longitudinal systems, is used in ironclad ships. This frame-work consists essentially of two sets of frames, crossing each other at right angles, or nearly so, the plates of the longitudinals being continuous, and those of the transverse frames in short pieces between the longitudinals. The plates in the transverse frames consist of a bracket-plate on each side of the longitudinal, to which they are riveted by means of short pieces of angle-iron. They are also riveted to the continuous reverse angle-iron of the transverse frame, and to the frame angle-iron, which generally consists of short pieces between the longitudinals. Frames connected with water-tight bulk-heads are provided with solid plates. The longitudinals are notched to receive the reverse angle-iron of the transverse frames. The inner skin forms a double bottom for a great portion of the length of the ship, the cellular spaces between being accessible, through man-holes, at all parts. The upper longitudinals extend the whole length of the ship, and turn into breast-hooks, and are arranged to partially sustain the thrust of the ram; the lower ones are stopped at various places, the lowest generally at the termination of the double bottom. Tons are placed above the armor-shelf. Some of the decks of ironclads, particularly armored decks below-water, are deflected near the bow so as to assist in sustaining the thrust of the ram.

All iron vessels should, when practicable, be provided with so many water-tight compartments that two of them can be filled without sinking the ship.—*Albert Aston, Chief Engineer U.S.N.*

SHIP-CANAL. A canal large enough for the passage of ships. See CANAL.

SHIP-CARPENTER. A carpenter who works at ship-building.

SHIP-CHANDLER. A merchant who deals in canvas, rope, tar, and the other supplies necessary to ships.

SHIP-CRAFT. An old word for navigation.

SHIP FEVER. Ship fever has many synonyms, such as "camp fever," "jail fever," "hospital fever," "putrid fever," "spotted fever," etc.

These terms all mean the same thing. Ship fever is *typhus fever*, and always seems to arise under the influence of the same causes.

Some writers of authority seem to have considered it doubtful whether typhus can be generated *de novo*, but that seems now to be entirely set at rest.

At present all admit that the poison, or morbific matter,—the *miasm* which engenders the disease,—can be spontaneously developed wherever great masses of human beings are accumulated, as in great centres of population, in armies concentrated in a place too small in relation to the number of persons, in prisons, and in ships,—crowd-poisoning, in fact. It also occurs in sparse populations, where the lodging and food, as well as the surroundings, are exceptionally bad, as in certain epidemics in Ireland and elsewhere.

This has been particularly the case in penal hulks, owing to overcrowding, causing vitiation of the air by organic impurities, accompanied by deficient ventilation, personal filth, and frequently by impaired condition of system in the prisoners, the result either of insufficient food, improper food, or of scurvy taint.

The improvement in sanitary knowledge has decreased the ravages of typhus enormously, and seems to prove its generation from either criminal or enforced neglect of proper prophylaxis. Hence penal hulks have gradually been abandoned, the reasons for using them being otherwise very good. Hospital-ships, like the "Dreadnought" in the Thames, when long in use come into the same category, and have to be abandoned.

The dreadful mortality in the old "Jersey" prison-ship was probably typhus, and people died there, without recognition or help, in a way that was a disgrace to all the officials concerned. Once developed, ship fever spreads by contagion. The attendants upon the sick may carry the contagion, while they are themselves well. Any

person may carry it who has been exposed to the atmosphere for a comparatively short time.

In ship, or typhus fever, each patient is a focus of infection,—certainly from after the end of the first week up to the period of convalescence. If the patient is confined to a close place, a very few minutes' exposure may enable a visitor to carry away the contagion in his clothing. Medical men, nurses, some prisoners, and other persons exposed to the disease, have been supposed to enjoy a certain immunity, but this idea is a fallacious one, and no one who is in contact with patients affected with it can be certain of exemption.

At the celebrated "Black Assizes" at Oxford; at the Old Bailey trials, in 1750, the prisoners, though apparently well themselves, carried out from their foul wards the seeds of deadly disease to the judges, jury, lawyers, witnesses, and audience.

As has been said, the ravages of typhus, or ship fever, are much less than was formerly the case, owing to enlightened views and proper laws, but they have been very dreadful within our own period. There were epidemics of it in the United States in 1837 and 1850, but it is rare in this country, and did not occur during our late civil war.

Most familiar to us is the "ship fever" which prevailed during the great immigration of the Irish consequent upon the famine of 1847. Our seaport hospitals were then filled to overflowing with "ship fever," and some of us had an opportunity of observing it.

In 1813 the Bavarian army was almost destroyed by this scourge.

In Mayence, in 1813-14, of 60,000 French troops in garrison, there died, of typhus alone, in six months, 25,000. At Metz, during the Franco-German war, it made great ravages. Instances of epidemics on board ship, within comparatively recent times, are too numerous to mention.

Typhus fever, or ship fever, is always popularly confounded with typhoid fever. Their non-identity was really established by Baron Louis, in 1829, and his doctrines were brought to America and established by Gerhard, of Philadelphia, in 1837.

The distinction between the diseases was not recognized in England until much later, and then not fully until Sir William Jenner published his investigations in the London Fever Hospital, an institution in which true typhus may always be found.

It is not necessary, in an article of this nature, to go into an elaborate discrimination between the two diseases, but only to draw a general comparison for those who are left to their own resources. As we have said, they were formerly considered identical, and only varying in severity. It was after medical science took a great step in advance, and in quite recent times, that the difference was admitted,—by some very reluctantly.

Typhus, or ship fever, is confined to no particular age. Typhoid fever seldom attacks those much past youth. The course of typhus is sooner terminated than that of typhoid. The temperature of typhus is higher at first, and falls more rapidly in recovery. The termination of typhus is generally within three weeks, while typhoid generally runs much longer. In typhus there is frequently—indeed, commonly—congestion of the lungs. In typhoid, bronchitis is more apt to occur. Fatal results, in cases of typhus, occur, on an average, about the fourteenth day, while in typhoid they are apt to occur after three weeks. In typhus the urine is albuminous in the early stages, and in typhoid this condition occurs, generally, towards the close. The glands of Peyer, and the mesenteric glands, are sometimes not at all affected in fatal typhus. The spots of typhus remain after death. The spots of typhoid do not.

There is almost invariably diarrhœa in typhoid fever, and there is almost always constipation in typhus.

It is not necessary to give the pathology of the two diseases in this article, but only again to state their non-identity, the misunderstanding of which has sometimes led to great sacrifice of life.

The means to be adopted in case of an outbreak of typhus on board ship, or elsewhere, consists in separation (such as putting on the spar-deck, in boats, etc.), aeration, disinfection, purification, quarantine of attendants, and, especially, in avoiding the establishment of foci.

Ship fever, or typhus, has a comparatively sudden invasion. There is pain and soreness in the back and limbs, a sense of fatigue, uneasiness of the stomach, want of appetite, nausea, mental depression and irritation, and inability to sleep. It is difficult, however, to fix the precise time of attack. After a longer or shorter period of the premonitions given above, the patient is seized with chilliness and increased debility, and is obliged to take to his bed. The cold stage varies in degree and duration, sometimes slight and sometimes severe and protracted, with pale, cold surface, shrunken and anxious features, frequent, irregular, feeble pulse, and great prostration. Death sometimes occurs in this stage, but this is rarely the case.

Generally, febrile reaction comes on, and fever is established, with the usual symptoms of that condition. The pulse is often full, with some strength, but easily compressible, and not so firm as in ordinary fevers of much less gravity.

Nausea and vomiting are often absent throughout the illness. In general, the bowels are costive and require medicine.

Even at an early period of the disease the face is dark red or of a peculiar dusky hue, with injected eyes and very marked congestion about the nares and fauces. The mind is always sluggish and the thoughts confused, even in slight cases, and the pain over the forehead is apt to be exceedingly severe,—described as "bursting."

These symptoms continue for several days, gradually increasing until the disease is at its height. The surface is now universally hot, with little disposition to perspiration, the heat being of that peculiar kind called calor mordax, which communicates to the hand of another a sense of pungency or burning.

The temperature rises to 104° or 106° F., and has been known to go as high as 109°. The pulse is now feeble and frequent, sometimes so rapid as scarcely to be counted. The respiration is also very frequent, and generally feeble and imperfect in the lower and rear portion of the chest. There is apt to be a slight remission of

fever in the early part of the day and an increase in the evening, while there is great stupor during both periods.

The peculiar eruption of typhus often occurs on the fourth or fifth day,—whence one of its names—"spotted fever." The spots are irregular and isolated, or else grouped in irregular patches, looking not unlike measles.

Soon after they appear they become permanent; that is, they do not disappear under pressure. They are confined to no particular part of the body, are light-colored in mild cases and dark in malignant ones; they are true *petechiæ*, in fact. They last 11 or 12 days, usually disappearing before convalescence begins. They are often accompanied or succeeded by the peculiar vesicular eruption called *sudamina*.

By the end of the first week, or when the disease is fairly developed, the tongue is brown and dry, and dark sordes collect upon the teeth, gums, and lips. Sometimes, but not frequently, the tongue seems deep red and glazed, looking like a piece of raw beef.

In typhus there is a total want of appetite; but food is borne by the stomach much more readily than in most other fevers. In exceptional cases the bowels may be loose; but usually they are only moved by medicine, and the dejecta are always dark and most offensive.

There is no marked tendency to tympanitis. The urine is generally very scanty. The dusky hue of the face grows deeper, with great suffusion of the eyes, and a peculiar and characteristic odor exhales from the body, which has been variously described. Some liken it to rotten straw, some to the smell of mice, but it is really *sui generis*, and most resembles that of confined apartments in which numbers of persons, whether sick or not, have been long crowded together without attention to cleanliness or ventilation. When once experienced the odor will always be remembered.

Even at the most grave period of the disease a patient may generally be roused from stupor and made to answer questions, but generally imperfectly and with reluctance. But often he sinks into *coma*, or has delirium, generally low and muttering, with twitching and jerking of the muscles, and picking at the bedclothes. If no favorable change takes place, the patient sinks into the last stage, that of complete prostration, slipping down in the bed, eyes half closed, mouth open, pupils dilated, or else very much contracted, hiccough, tongue like a brown, dry chip, inability to swallow, involuntary discharges from the bowels, suppression of urine, and insensibility of the skin to irritants, coldness of surface, collapsed, ashy face, and pulse imperceptible at the wrist.

No case must be considered hopeless, however, until life is extinct, as wonderful recoveries from this disease have occurred. In fact, it has been regarded as almost a peculiarity of the disease, that persons have been left to die during epidemics, and have been found sitting up and eating the food left beside them.

Sometimes, and generally about the fourteenth day, amelioration of symptoms takes place. The pulse falls, the skin relaxes, the tongue becomes moist and begins to clean, the eruption fades gradually, and the nervous twitchings subside and consciousness returns. This is often preceded by a profuse perspiration, or an unusually profuse discharge of urine. The patient frequently falls into a sound and prolonged sleep, and wakes up a new man. The recovery in such a case is usually rapid; the appetite is often insatiable, and, if indulged in, is apt to lead to relapse.

When recovery takes place from a low condition or from collapse, it is always slow. Supporting remedies must be used, for there is extreme debility to be overcome. The hair is apt to come out, and the skin to peel. The brain and nervous system are slow to recover tone, and the intellect, especially the memory, remains imperfect for a long time. Relapses are rare under proper treatment, and ultimate recovery is generally perfect.

The duration of ship, or typhus fever, is variable. When it terminates favorably it runs a course of about three weeks,—one week in development, one in the formed state, and one in the decline.

It may, if mild, terminate earlier. Some cases run on longer than 21 days. Fatal cases may end at any period. Death sometimes occurs, without reaction, within the first 24 hours. This, of course, is where great susceptibility receives a tremendous dose of the poison. It is not unusual for death to occur about the fifth or sixth day, but usually it takes place some time in the second week, say from the ninth to the twelfth day. Of course it may occur at a much later period.—*E. Shippen.*

Ship-keeper. A watchman employed to take care of a ship when laid up, or in ordinary. An officer who remains much on board.

Ship-language. Language current among sailors.

Ship, Launching of. At the commencement of the building of a ship, the foundations are laid with a view to her launching, and the difficulties to be overcome in the particular situation in which the work is to be performed, are carefully considered and provided for.

Particular care must be taken that the foundation is sufficient to bear the whole weight of the fabric, so that no settling may occur at any time during the progress of the work, or at the time of launching.

If the location requires it, piles are first driven both under the keel and the launching-ways the whole length of the ship, and under the extension of the launching-ways, as far out into the water as is necessary to extend them, that the ship may be floated. Upon these piles, under the keel, are placed the ground-ways, and upon the top of the ground-ways blocks are laid, about 5 feet apart, for the whole length of the ship.

On the top of these blocks, before the keel is laid, other blocks are placed, made wedging, athwartship, from 2 to 3 feet long. These blocks should be carefully selected with reference to the grain of the wood, so that they may be easily split at the time of launching the ship. Upon these blocks the keel rests. The height of this foundation should be laid with reference to the work which is to be done under the bottom of the ship, as well as the descent of the ship into the water. The blocks are laid upon an inclination of from $\frac{5}{8}$ of an inch to 1 inch to the foot.

Great care should be taken in laying the keel, that the forefoot shall not strike the ground-ways

in launching, allowance being made for the settling of the ship during that process.

While the ship is building her weight rests upon the blocks under the keel, and such shores as may be needed under the bilge and sides. When the time of launching comes this weight is to be transferred from these keel-blocks to inclined planes, which are placed one on each side of the keel, called "launching-ways."

These are securely placed upon the top of the "piles" previously prepared and the blocking necessary to bring the ground-, or lower ways, to the required height and inclination.

The surface of these ways should be calculated with reference to the amount of friction coming from the weight to be placed upon them. And it is a good fault that the ways are too wide rather than too narrow.

The ground-ways having been placed, they may be carefully smoothed and laid with precision, either to a gentle curve or a straight line, their entire length, and when ready they may be coated with a preparation of tallow, lampblack, castile soap, and oil in suitable proportions. The sliding-ways may now be hauled up and fitted.

In putting together the sliding-ways, take care that the thin part of the snape comes aft, and that everything is removed that may cause the bilge-ways to catch when the movement commences.

After the sliding-ways are fitted, a ribband is secured to the outside of the ground-ways. Packing, shores, and poppets are built up on the top of the sliding-ways to fit the bottom of the ship, leaving an opening of from 4 to 6 inches, for wedges, between the sliding-plank and the packing,—these wedges being for the purpose of lifting the ship from the keel-blocks and transferring the weights to the sliding-ways. The packing spoken of may be carried as far forward and aft as the sliding-ways, or as far as the shape of the ship will permit.

If poppets or short shores are used, they should be secured at the ends to each other and to the plank above the wedges, in order that it may be like a solid mass of wood, trussed and secured with chains under the keel, from side to side.

The ribbands having been secured to the ground-ways, and the whole of the new fabric upon which the ship is to rest well shored and braced, the foundation is complete for transferring the weight of the ship from the keel-blocks to the launching-ways.

While the packing or chocks are being fitted, wedges of large size are fitted between these chocks and the sliding-ways fore and aft, close together.

When this work is all done it is usual to shore up and secure the packing to the bottom of the ship, and push the sliding-ways in toward the ship, in order to give them a final coat of the launching composition of tallow, oil, soap, etc. The sliding-ways being thoroughly coated, they are pushed back into their places and the wedges inserted fore and aft, leaving about one-half of their length outside of the packing. The ends of the launching-ways are now secured to the ground-ways.

The anchors being ready for letting go, and every arrangement having been made which is necessary to check the vessel after she has left the ways, the word is given to "wedge up." The men, provided with heavy sledges or battering-rams, wedge up on both sides for a sufficient time to raise the whole mass slightly from the keel-blocks, and the weight is thus transferred to the sliding-ways.

Now commences the exciting part of the launch. The blocks are removed one by one, commencing at the after end, usually by splitting out the wedge-pieces next to the keel; and as fast as the blocks are removed and cleared out of the space between the sliding-ways, the bilge- and wale-shores are removed. When all the blocks are out, the plank, or trip, which is the forward end, is all that holds the ship from sliding.

The word is now given to "cut away," and the men have hardly cut off the plank, inch by inch, before the whole mass starts for its native element, amid the cheers of those who may be in attendance.—*S. H. Pook, Naval Constructor U.S.N.*

Ship, Log-. The log-chip. See Log.

Ship-lord. An old term for the owner of a ship.

Shipman. An old term for a mariner.

Shipman's Card. An old name for the compass.

Ship-master. The captain, master, or owner of a merchant ship.

Shipmate. A fellow-sailor. One who serves on board the same ship.

Ship-money. Money exacted illegally by Charles I. of England to fit out ships in time of peace.

Ship-owner. One who owns ships.

Ship-pendulum. A pendulum to show by its oscillations the roll and pitching motion of the ship.

Shipper. One who embarks freight in a ship.

Shipping. Vessels generally. The whole body of ships in a place.

Shipping-articles. Articles of agreement between the master and seamen with regard to wages, length of time of service, etc.

Shipping-master. A person legally appointed to superintend the shipping of seamen for the merchant service.

Ship-rigged. Rigged like a ship, with three masts, all provided with yards, and spreading square-sails.

Ship's Boats. The boats belonging to the ship.

Ship's Books. The books of the executive and of the paymaster, in which the names of the men are borne.

Ship's Company. The crew of the ship.

Ship's Cook. See Cook.

Ship's Corporal. A petty officer, whose duty is to assist the master-at-arms in preserving order, arresting offenders, etc.

Ship's Days. The lay-days allowed to a ship for loading or unloading cargo.

Ship-shape. In a seaman-like manner. Neat and thoroughly done.

Ship's Husband. The agent or broker who manages her accounts with regard to repairs, etc., while refitting.

Ship-sloop (*Eng.*). A sloop rated as a ship, because commanded by a captain.

Ship-star. An old name for the *pole-star*.

Ship's Writer. A petty officer who, under the directions of the executive-officer, does the

writing and keeps the watch-, muster-, conduct-, and other books of the ship.

SHIP-TIMBER. Timber to be used for ship-building.

SHIP-WORM. A mollusk, of the genus *Teredo*, that burrows in timber, secreting a calcareous shell as it goes, and weakening the wood.

SHIPWRECK. The destruction of a ship by being cast ashore on shoals or rocks; a ship that has been wrecked. See WRECK.

SHIPWRIGHT. A builder of ships.

SHIP-YARD. A dock-yard; a yard where ships are built or repaired.

Shiver. A sheave. *To shiver a sail*, to luff the ship, or brace the yard, so that the wind, acting on the edge of the sail, causes it to shake.

Shoal. A school of fish. A shallow or bar where the water is not deep. To become more shallow.

SHOAL-INDICATOR. A buoy placed on a shoal.

SHOALED-HARBOR. A harbor secured from the violence of the sea by banks, bars, etc.

Shock, William H., Chief Engineer U.S.N. Chief of Bureau of Steam Engineering. Born in Maryland. Appointed from Maryland, January 18, 1845; entered the naval service as third assistant engineer, during the Mexican war, served on board the steamers "General Taylor," "Princeton," "Spitfire," and the frigate "Mississippi," in which vessels, at different periods, he participated in the capture of Tampico, under Commodore Connor, and Alvarado, Tuspan, Tlacotalpan, and Vera Cruz, under Commodore Perry.

Promoted to second assistant engineer, July 10, 1847; ordered to the steamer "Engineer," Home Squadron.

Promoted to first assistant engineer, October 31, 1848; 1849, was senior engineer steamer "Legaré," coast survey; 1850–51, special duty at Philadelphia, superintending construction of machinery of steam-frigate "Susquehanna."

Promoted to chief engineer, March, 1851; 1851–52, special duty, Boston, Mass., superintending construction of machinery of steamer "Princeton"; 1853–54, inspecting engineer of ocean steamers for U. S. mail service, and chief engineer of steamer "Princeton," Home Squadron; 1854–55, West Point, superintending construction of machinery for steam-frigate "Merrimac"; 1855–56, chief engineer steam-frigate "Merrimac," Home Squadron; 1857–60, chief engineer steam-frigate "Powhatan," East India Squadron; 1860–62, president of Examining Board of Engineers; 1862–63, special duty at St. Louis, superintending construction of river monitors; 1863–65, fleet-engineer, West Gulf Squadron, participating in the capture of Forts Gaines and Morgan, under Admiral Farragut, and the Spanish Fort and city of Mobile, under Admiral Thatcher; 1865–66, chief engineer of Boston Navy-Yard; 1867–68, chief engineer of Washington Navy-Yard; 1868–69, fleet-engineer of European Squadron; 1869–70, inspector of machinery afloat, and member of Board of Visitors to Naval Academy at Annapolis, Md.; in the summer of 1870 was appointed acting chief of Bureau of Steam Engineering, retiring from the office with the written thanks of the Department for the efficient manner in which the duties of the bureau were discharged; in 1871 was again called to take temporary charge of the Bureau of Steam Engineering, and on retiring from the position was actively employed on other duty in the United States until 1873, when he was ordered to Europe on a tour of inspection of public and private dock-yards, and to represent the Bureau of Steam Engineering at the International Exhibition at Vienna, and by direction of the President was appointed one of the American Judges of Awards; returning from Europe, was detailed to other duty until March 3, 1877, when he was appointed and confirmed engineer-in-chief of the U. S. navy.

Shod. An anchor is *shod* when the fluke is covered with mud that has adhered to it.

Shoe. An iron arming to a hand-spike. A board hollowed slightly, and placed under a sheer-leg, to serve in transporting it. The outer piece of the forefoot. A flat block of hard wood, hollowed to receive the ear of an anchor-fluke. It slides up and down the bows, with the inner fluke resting in it, so as to prevent the anchor from tearing a hole in the bow. A triangular plank structure placed over the fluke to increase its area. *Magazine shoes* are of canvas, to be worn in the magazine. *To shoe an anchor*, to place over the palms projecting pieces of hard wood, secured by hoops and nails, so as to give greater holding-power in soft mud.

Shoe-block. A block consisting of a single piece of wood, without a strap, with two sheaves inserted at right angles to each other. They are used for main-buntline blocks.

Shoë-paun-dogee. A gorgeous imperia. yacht used by the emperor of Burmah on ceremonial occasions. It has a very high curved stern, a griffin terminates the bow, and a richly-gilded house is built on the deck.

Sholes. Pieces of oak placed under the soles of the shores while the ship is building; they are used to increase the surface under the shore so as to prevent its sinking into soft ground.

Shoot. To move rapidly; as, a ship "shoots ahead," etc. To pass rapidly through or by; as, to shoot a rapids, or a bridge. *To shoot a net*, to run it out into the water. *To shoot the sun*, to take its altitude. *To shoot the compass*, to go wide of the mark.

Shore. The littoral of a country. That part near the ocean. *Bold shore*, a high, steep shore. *Flat shore*, a low, flat coast. *Shelving shore*, a gradually descending coast.

A prop to support anything from below. *Bilge-shore*, a shore under the bilge. *Cap-shore*, a short support under the mast-cap. (See CAP-SHORE.) *Breast-shore*, a shore near the middle of the ship, extending abeam. *Wale-shores*, shores supporting the ship at the wales, extending vertically downwards. *To shore up a ship*, to place shores under a ship's bottom.

SHORE-ANCHOR. The anchor lying toward the shore.

SHORE-BOAT. A private boat belonging ashore.

SHORE-CLEATS. Heavy cleats nailed to the side of a ship, against which shores rest.

SHORE-DUTY. Service on shore, as distinguished from service afloat. Duty at navy-yards, Navy Department, etc.

SHORE-FAST. A hawser or chain securing a ship to the shore.

SHORE-PAY. The pay of an officer when on shore-duty. In the U. S. navy it varies from six- to eight-tenths of the highest pay.

SHORE-REEF. A fringing-reef.

SHORE-STATION. A naval establishment on shore.

Short. *To heave short*, to heave in on the cable until it is nearly up and down, or until the anchor just holds, without any slack cable. *Short-apeek*, up and down, applied to the cable of an anchor. *Short allowance*, a reduction of provisions, water, etc., in case of necessity. *Short board*, a short run on one tack, when circumstances preclude the use of longer intervals between tacks. *Short glass*, the 14-second glass, used with the log. *Short-handed*, deficient in men. *Short-linked chain*, chain without studs, and with short links. *Short sea*, a confused, tumbling sea. *Short-service*, service placed on a hemp cable for riding at a short stay. *Short stay*, that position of the cable when it is nearly up and down, or when the anchor is nearly atrip.

SHORTEN. To *shorten in* on the cable is to heave in to a shorter scope. *To shorten sail* is to reduce the amount of sail by taking in some of them; to haul up or take in all sail when set or loosed to dry.

SHORT-SHEET. The shorter of the two sheets fitted to a topmast stun'sail. When the sail is set, it is led through a thimble on the lower yard into the top, where it is belayed.

SHORT-SPLICE. A short union of two ropes, used when an increase of the diameter is not inadmissible.

Shot. The union of two or more cables, for greater length, form a *shot* of cable. The reckoning or expense. A place where fishermen draw their nets. The sternmost part of a fishing-boat. A kind of trout. To load a gun with shot. See PROJECTILES.

SHOT-GARLAND. See GARLAND.

SHOT-GAUGE. A gauge or calliper to measure the dimensions of shot.

SHOT, GRAPNEL-. A shot with a grapnel attached, carrying a line, to be used in communicating with ships in distress.

SHOT-LOCKER. A strongly-built locker in the hold, to contain shot. *Shot in the locker*, money in the purse.

SHOT-PILE. A pile of shot in a navy-yard or magazine on shore. Shot are carefully piled on masonry or wooden platforms. The number of shot in a pile is found by multiplying the sum of the three parallel edges by the number of balls in a triangular face.

SHOT-PLUG. A wooden plug used in connection with fearnaught for stopping shot-holes.

SHOT-PROP. A wooden prop covered with tarred hemp, used to stop a shot-hole from the inside.

SHOT-RACK. Iron rods fitted about the hatches, water-ways, and on the berth-deck, to contain shot.

SHOT-TROUGH. Wooden troughs placed about the decks to convey shot during action.

SHOT-WAD. A wad of hay or junk placed in front of a shot to hold it in place in the bore.

SHOT-WHIP. A whip for hoisting shot from the locker.

Shotten Herring. Cleaned herring for drying. A lean, lazy fellow.

Shoulder. The projecting portion of a ship about the water-line, that gives her stability under canvas. A ship it said to *shoulder the anchor* when she drags it in consequence of having too little cable out.

Shoulder-block. A block with a shoulder or square projection at the upper end, to keep it in an upright position.

Shoulder-knot. An ornamental knot of gold lace, worn on the shoulder in lieu of strap and epaulet. Officers of the grades of ensign and midshipman, and corresponding grades in the staff corps, and company officers of the marine corps, wear shoulder-knots.

Shoulder-of-mutton Sail. A triangular sail attached to a mast, and used in boats.

Shoulder-strap. A narrow strap of cloth worn on the shoulders by all commissioned officers above ensign in the navy, and assimilated ranks, and all field-officers in the marine corps. In the strap distinguishing ornaments are worn, as follows: all line-officers, an anchor in the centre or at each end; master, one gold bar at each end; lieutenant, two gold bars; lieutenant-commander, one gold leaf at each end; commander, one silver leaf; captain, silver eagle in the centre; commodore, one star in the centre; rear-admiral, one star at each end; vice-admiral, three stars; admiral, four stars. Officers of the staff corps substitute for the anchor: medical officers, a blank; pay-officers, an oak sprig; engineer officers, four oak leaves in a cross; naval constructors, two oak leaves and an acorn in gold; chaplains, a silver cross; professors, one oak leaf and an acorn; secretaries, the letter S in silver. See UNIFORM.

Shout (*Eng.*). A light flat-bottomed ducking-punt.

Shoveler. A duck (*Anas clypeata*), with a broad bill.

Show Leg! "Turn out quickly." An expression used to get the watch out of their hammocks.

Shrab. A Calcutta drink.

Shrapnel. A species of shell, devised by Gen. Shrapnel, also called spherical case. They are thin shell, being one-tenth of their diameter in thickness. They contain a bursting charge of powder only sufficient to burst the shell, and a quantity of sulphur, in which a number of balls, from .65 inch to 1 inch in diameter, are imbedded. They are cast like shell. Their use is effective against boats or bodies of men, at considerable distances. They are boxed and have sabots like shell, but the boxes are painted white. Those for smooth-bore guns and howitzers have Bormann fuzes. They are not yet used in rifle-cannon in the U. S. navy. *English shrapnel*, also called *diaphragm-shrapnel*, have a thin iron partition separating the bullets from the bursting charge.

Shrimp. The *Crangon vulgaris*, a crustacean used for food.

Shroud. A rope belonging to the standing rigging of a ship, generally alluded to in the plural. Each shroud is connected with another so as to form a *pair*. They are made of shroud-laid tarred hemp rope, or more commonly now, of wire rope. A collar is formed by a seizing that embraces the mast-head. In the end of each leg of a pair is placed a dead-eye, or a rigging-thimble, or it embraces the upper part of a rigging-screw, as the case may be. It is fastened by laniard or screw to the chain-wales, and the shrouds, being set up, support the mast sideways. When there is an odd number of shrouds, the forward or after one is the odd one.

The forward shroud is called the *swifter*. Shrouds after being cut, when of rope, are wormed, parceled, and served where the eyes are formed, and swifters, all the length; when of wire, they are red-leaded, wormed, and parceled, again red-leaded and served full length. Shrouds are variously named from the spars they support.

SHROUD-BRIDLE. A bridle formerly placed in the shrouds, with a thimble in the bight, through which the lower sheets led.

SHROUD-CLEAT. A wooden or iron cleat, seized to a shroud, to belay a rope to.

SHROUD-KNOT. A knot formed in a shroud that has parted.

SHROUD-LAID ROPE. Right-handed four-stranded rope, with a heart.

SHROUD-PLATES. Iron plates extending from the dead-eyes to the ship's side.

SHROUD-ROPE. Superior rope for shrouds and stays, of the best Russian hemp.

SHROUD-STOPPER. A rigging-stopper. See STOPPER.

SHROUD-TRUCK. A fair-leader, or short wooden cylinder, having holes in it for rigging and a groove and score, the latter embracing the shroud, and the former filled by a seizing, fastening it to the shroud.

SHROUD-WARP. See WARP.

Shubrick, the name of several gallant officers of the U. S. navy, natives of South Carolina, sons of Col. Thomas Shubrick, aid to Gens. Greene and Lincoln in the Revolutionary war, born 1775; died at Charleston, S. C., March 4, 1810.

John Taylor, born September 12, 1788; died July, 1815; midshipman, June 20, 1806; lieutenant, May 28, 1812. He was in the "Chesapeake" in her affair with the "Leopard," in 1807; in the action of the "Constitution" with the "Guerriere," in August, and with the "Java," December 29, 1812; of the "Hornet" with the "Peacock," February 24, 1813 (for which he received medals from Congress); of the "President," when captured by a British squadron, in January, 1815, and on the conclusion of peace was dispatched to the United States in command of the "Epervier" with the treaty. This vessel was never afterward heard from.

William Branford, born October 31, 1790; midshipman, June 20, 1806; lieutenant, January 6, 1813; commander, March 28, 1820; captain, February 21, 1831; rear-admiral (retired list), July 16, 1862; commanded battery of one gun on Craney Island in the repulse of the British forces, June 22, 1813; lieutenant in the "Constitution" in action with the "Cyane" and "Levant," February 20, 1815; commanded squadron in the Pacific in 1847, and captured Mazatlan and other ports from the Mexicans; commanded Brazil Squadron and Paraguay Expedition, 1859; chairman Light-House Board, 1860–70.

Edward Rutledge died at sea, March 12, 1844, at about 50. Midshipman, January 16, 1809; lieutenant, October 9, 1813; commander, April 24, 1828; captain, February 9, 1837; served under Commodore Rodgers in the war of 1812–15; appointed to command the "Columbia," Brazil Squadron, May 4, 1842.

Irvine, born in 1797; died in Philadelphia, April 5, 1849. Midshipman, May 12, 1814; lieutenant, January 13, 1826; commander, September 8, 1841; served under Decatur in the action of the "President" with the British squadron in 1815; also in the war with Algiers in 1816; as first lieutenant of the "Potomac," in 1832, headed the sailors and marines in the destruction of Quallah Battoo.

Shufeldt, Robert W., Commodore U.S.N. Born in New York. Appointed midshipman from New York, May 11, 1839; first cruise in the frigate "United States," Pacific Squadron, 1839–41; in brig "Bainbridge," Home Squadron, 1842–44; at Naval School, Philadelphia, 1844–45.

Promoted to passed midshipman, July 2, 1845; on the coast survey in 1845–46; in frigate "United States," Mediterranean Squadron, 1846–47, and sloop "Marion," same squadron, 1847–48; in mail-steamer "Atlantic," 1849–50.

Promoted to master, February 21, 1853.

Commissioned as lieutenant, 1854; resigned, June 20, 1854. (While out of the navy he was active in the organization of the steam commercial marine of New York. Served two years in the Collins line of Liverpool steamers, as chief officer; superintended the building of and commanded the steamers "Black Warrior" and "Cahawba," between New York and New Orleans; was engaged for a year in the effort to open a transit across the Isthmus of Tehuantepec. At the commencement of the war, was commanding the steamer "Quaker City," between New York and Havana, when he was appointed consul-general to Cuba by President Lincoln; served in that office for two years, under difficult and trying circumstances, with the entire approbation of the government. He resigned in April, 1863, and accepted a commission of commander in the navy, previously tendered.)

Reinstated and received commission as commander, dated November 19, 1862. In May, 1863, commanded steamer "Conemaugh," South Atlantic Blockading Squadron; was present and participated in the capture of Morris Island, and in several of the attacks upon Fort Wagner; commanding steamer "Boteus," East Gulf Blockading Squadron, 1863–65; commanding steam-sloop "Hartford," flag-ship East India Squadron, 1865–66; commanding steam-sloop "Wachusett," Asiatic Squadron, 1866–68; commanding naval rendezvous, New York, 1868–69.

Commissioned as captain, December 31, 1869; commanding monitor "Miantonomah," 1870; commanding Tehuantepec and Nicaragua Surveying Expedition, 1870–71; commanding "Wabash," flag-ship European Squadron, 1871–72; navy-yard, New York, 1872–74; chief of Bureau Equipment and Recruiting, 1875–78; commanding "Ticonderoga," special service, 1879–80.

Commissioned as commodore, September 21, 1876.

Shurgnee. A damp southeast wind in the Persian Gulf, preceded by heavy dews.

Sick-bay. This term is used for the hospital in the navies of English-speaking people. We understand by it a separate apartment, wherever situated, on board ship, for the reception and treatment of the sick and wounded.

Few single-decked vessels in our navy have any sick-bay, or hospital, at all, the sick being slung up to the beams, in their hammocks, or cots, anywhere about the berth-deck where they will be most out of the way. During the day they unavoidably suffer from noise, constant col-

lision with their swinging-beds, and the heat and odors of cooking from the galley. At night every inch of the space about them is occupied; the air is mephitic, and, when the watch is relieved, the noise and jostling of hammocks recurs. To reach a sick man in his "billet," the medical officer, or apothecary, or nurse must frequently pass under other hammocks, disturbing those well men who need their rest, or other invalids.

All frigate-built ships, and some corvettes or sloops-of-war, have sick-bays, and almost invariably these have been placed on the lowest inhabited deck, and in the extreme forward end of the vessel,—about the worst possible place for sick men.

The chief requisites for a hospital, or receptacle for sick and wounded, either ashore or afloat, are, in addition to proper shelter from the weather, the best attainable quietude, ventilation, and natural light.

These requisites have been systematically ignored in our navy, and, until quite recent times, in most other navies. In most of the latter more enlightened views now prevail, however, the French having led the advance. This being the case, it is altogether possible that our navy will, in due time, and in types of vessels permitting it, follow an excellent example, and remove the hospital from the berth-deck.

The usual position of the "sick-bay" (said to be so called because it made people sick) appears to be a traditional arrangement, derived from the galley period, through the French, and thence to us through the English, who derived many of their ideas in naval architecture from study of the vessels captured from their neighbors across the Channel.

Henry Teonge, a chaplain in the British royal navy more than two centuries ago, who kept a very minute diary, makes particular mention of sickness and mortality on board three large frigates, and yet never hints at the existence of any sick-bay or hospital. It is, therefore, to be supposed that there was no place set apart for the purpose in the English navy at that time.

Fonssagrives—one of the best authorities upon the subject—says that from all time the forward part of the ship seems to have been devoted to the sick, and that it was so devoted when rude manners and ideas saw in the sick only useless encumbrances, and when *væ ægrotantibus* seemed as natural as the *væ victis* of the ancients.

These quarters were given to the sick, then, not as the most suitable for them, but with a view to isolate them, and thus to preserve the rest of the ship's company from contagion,—often of plague, or of ship fever,—putting them somewhere where well men would not be obliged to touch them, or pass them. The only other place where these conditions could obtain—the stern of the vessel—was already occupied by the commanding officer.

Jean Marteilhé, of Bergerac, tells us that in the French royal galleys of the 17th and 18th centuries, the compartment in the bows, under the low deck of the galley's prow, beneath the water-line, close, dark, and dismal, served for the combined purpose of stowing the cables and the medicine-chest, and here, upon the cables, were piled the sick,—if they were allowed to leave the oar at all,—as well as those wounded in battle; so that great mortality ensued. "The wounded died like flies," he says.

M. Jal also alludes to the hospitals of fighting-galleys, of an earlier period, which he says were in the forward part of the vessel, and called, at that time, "tollar," from *tolerare*, to suffer. "It was there the sick suffered."

Smollett, writing of the Carthagena Expedition, 1741, says that the hospital of the man-of-war in which he served was three degrees more offensive and more suffocating than the cock-pit,—then, and long after, the quarters of the surgeon's mates, as has been the case in our navy within twenty years.

In the French navy of more modern times the traditional practice of placing the sick on the lower deck, forward, seems to have been first broken in upon about the year 1810, when strong remonstrances against its impropriety and impolicy—cruelty, indeed—caused important changes to be inaugurated, and these have been permanent.

It is, however, within quite recent times that the sick-bay has been taken from the berth-deck, in double-decked vessels of the English navy, and it never has been done in the U. S. navy, except in some receiving-ships, which are not in any sense sea-going vessels.

As a precaution and temporary measure, in cholera, yellow fever, and other epidemics, or in case the wounded were so numerous as to overflow the limits of the "sick-bay," they have been placed upon the gun-deck or elsewhere. Still, with us, the old sick-bay, in the most dismal part of the ship, is the only recognized official hospital on board. The usual position of our "sick-bay" is objectionable for many reasons. Ventilation is bad, at the very best. Light is defective in the extreme. The air-ports, of which there are seldom more than two, of a few inches diameter, are seldom open, except in a calm, or in a close harbor. As a rule, candles are used to examine patients, and even to perform important operations. Ether must be used with care in artificial light, otherwise there is danger to the ship and all on board.

The chains are worked just above the sick-bay. The ship's bell is generally so hung that its jarring tones are more distinctly heard in the sick-bay than anywhere else. The chatter and noise of the berth-deck cooks, and the smell of onions, garlic, and other ingredients of nautical "scouses," is generally more perceptible in the sick bay than anywhere else.

Since the abolition of flogging prisons have become more necessary, and these are now generally built against the after part of the sick-bay. Sometimes they encroach upon its scanty air-space. Here drunken, noisy men are apt at times to be confined. There is also unavoidable damp and leakage, from the working of the head; the water often trickling down the breast-hooks, or filtering down from the gun-deck, after seas are shipped into the manger, through the hawse-pipes.

At sea, or even at anchor in roadsteads and other exposed places, with fresh winds and rough water, the monotonous, pile-driving blows of the sea against the bows are almost sufficient to distract a well man, let alone a patient in hospital.

Our merchant vessels long ago removed their crews from the holes called forecastles, which

answered, in most respects, to the usual position of our sick-bay.

Serious attention has been given to this important matter by many of the naval medical officers, who have made frequent and urgent reports upon the subject, especially Medical Director A. L. Gihon; while Admiral Leroy, Admiral Porter, and Commodore Shufeldt have officially recommended a change. Their exertions in this direction are worthy of all praise, and may, eventually, be successful in accomplishing a reform called for by considerations both of humanity and expediency.

With a *personnel* crowded in the extreme, far beyond all sanitary limits, there is, on the berth-deck of a man-of-war, a permanently contaminated atmosphere which is never very much improved during a cruise, from the impossibility of evacuating and thoroughly cleansing the deck, even in the daytime. Even if evacuation could be accomplished, the means of thoroughly renewing the air is practically, in most cases, nearly wanting.

The air-ports do not accomplish it, nor do wind-sails, and, in some cases, patent apparatus has done more harm than good, while other apparatus have been rejected on account of the expense, as if any cost could be too great for machinery which accomplished this all-important purpose. Army and navy men, and many in civil life, are continually grappling with the difficult question of the disposition of the emanations from healthy human bodies alone, and the question has not been solved. Should we, then, expose the sick to these emanations, or the well to those of the sick? Would any one who could live elsewhere live in a damp and unventilated back cellar? And yet this is about the relative position of the sick-bay in our men-of-war, where the sick and wounded are not afforded the best chance of recovery.

As has been stated, the sick-bays in the French and English navies are now generally upon the gun-deck; either arranged with movable, latticed bulk-heads and placed amidships, or on each side, taking in about two gun-ports, the guns being slewed round, and lashed against the side, but not removed. In case of action they are readily brought into service, and their crews are exercised at other guns. A favorite way in the French navy was to have the sick-bay forward upon the gun-deck, bulk-headed with latticed windows, and embracing the bridle-ports, which, being mostly kept open,—even at sea in fair weather,—were a fine source of light and air.

They had, generally, glass windows for these ports: to be used in cool weather. Here was light, ventilation, and cheerfulness secured. The chains, in this case, were worked by oblique hawse-pipes underneath the sick-bay.

(Nothing would be interfered with but the traditional chicken-coops and live-stock in the manger, which pollute our gun-decks yet.)

In our navy the *personnel* of the sick-bay, besides the medical officers in charge, are the apothecary, whose dispensary, in double-deck ships, is often 100 feet or more from the sick-bay, while the medical store-room is elsewhere, either in the darkest part of the cock-pit, or in the shaft-alley, probably to the great detriment of stores and medicaments which, upon a sudden emergency, may be of the highest value, and exposed, more or less, to pilfering.

The apothecary is fairly paid, and ranks as a petty officer.

The attendants upon the sick are now called "nurses" and "bay-men." They are generally selected from the crew, paid as landsmen, and usually without any experience, either in nursing or cooking. The apothecary, nurses, and bay-men are selected by the senior medical officer. In the case of the apothecary, he is appointed, under certain regulations, with the approval of the commanding officer. The nurses and bay-men may be appointed in the same way, but this is generally not the case, they being picked up from among the landsmen.

On board ship men whose sickness is slight are only put upon the "binnacle list." In well-regulated sick-bays they are not allowed to take up the limited air-space by spending their time there, except while being prescribed for or receiving medicine.

More serious cases are put upon the "sick list," and generally allowed to have their hammocks down in the daytime, should the medical officer consider it necessary. Important cases of illness, or surgical cases of gravity, have cots slung for them, which afford a very fair degree of comfort. Standing beds, of iron, swung to upright posts, with gimbals, have been used, in some cases with approval, in our sick-bays. Fleet-Surgeon Foltz, who served in the operations under Farragut in the "Hartford," always spoke most highly of them. But there are serious objections to their use, not necessary to be entered upon here, in the confined space at present allotted to the sick-bays.—*E. Shippen.*

Sick-berth. A place temporarily screened off to accommodate sick men.

Sick-book (*Eng.*). An account of sick persons on board, or sent to the hospital.

Sick-flag. The yellow quarantine-flag. In the English service there are two other sick-flags, one yellow with a black ball, the other with a square in the centre, used to denote the presence of contagious diseases.

Sick-leave. Leave of absence given on a surgeon's certificate of disability, or on medical survey.

Sick-list. The list of sick, with their complaints and condition, sent in daily to the commanding officer by the surgeon. A duplicate list of names only, posted on the upper deck, is called the *binnacle-list.*

Sick-mess. The mess for the sick, partly provided by the surgeon's department.

Sick-ticket. A paper which is sent with a patient to a hospital, giving rank, description, disease, etc.

Side. The side of the ship includes all the outside upper works from the gunwale down to the main-wales, where the bottom commences.

Side-boys. Boys detailed to attend at the gangway, on the approach of officers, dignitaries, etc. By the regulations of the navy, side-boys may be called as follows: for admiral and vice-admiral, 8; rear-admiral or commodore, 6; captain and commander, 4; all other officers, 2. This time-honored custom is gradually falling into disuse.

Side-cleaners. Men detailed to keep the side clean, sweep out channels, etc. These are

chosen from each part of the ship in rotation, and clean their own parts.

Side Counter-timber. The stern-timber resting on the wing-transom, and extending to the upper rail.

Side-curtains. The awning curtains.

Side-ladder, or Accommodation-ladder. A staircase fitted to ship and unship, used at the gangways on the outside of large ships. On steamers it is usually a short ladder, tricing up at the lower end when not in use.

Side-lights. Lanterns used at the gangway at night. The *running lights* placed on either side of the ship, green and red in color.

Side out for a Bend (*Eng.*). In coiling a cable, to draw outside the last turn, to begin a new sheave, or tier.

Side-screens. Screens of canvas placed about the side-ladder.

Side-steps. Pieces of wood bolted to the ship's side at the gangway, serving as steps to ascend the side.

Side-stops. Stops fastened to the side-ropes of an awning, to spread it to the ridge-rope.

Side-wind. A wind from one side, so that the ship may lay her course, but the yards are braced in more or less. A wind blowing from one point forward to three points abaft the beam.

Side-beam Engine, or Side-lever Engine. A form of marine steam-engine in which the motion is transmitted from the piston-rod cross-head by *side-rods* passing downward on each side of a vertical cylinder to a pair of *beams* or *levers* working at the sides of the bed-plate near the bottom of the vessel, and from thence, through the cross-tail and connecting-rod, upwards to the crank. The object of the arrangement is to secure conciseness and enable the engine to be placed low in the vessel and well protected below-decks. It is used for paddle-wheels only. The form is nearly obsolete.

Sidereal (Lat. *sideralis*, from *sidus*, *sideris*, a star). Pertaining to the stars. See Day, Time, Year.

Side-keels. Keels on either side of the centre line of the ship's bottom. Used in small vessels, to give greater stiffness to them.

Side-keelsons. Sister, or side-keelsons, are additional to the main keelson, and are used especially in light-draft vessels to add to the stiffness of the main keelson, when it has not sufficient depth.

Side-lever. One of the *beams* of a side-lever engine. A lever working at the side of any machine.

Side-rod. One of the rods connecting the cross-head of a steam-engine to a side-lever. In back-acting screw-propeller engines having a single piston-rod, the rods or bars connecting the piston-rod cross-head with the connecting-rod cross-head are called *side-rods*.

Side-sights. Sights for a cannon placed at the side of the breech, and on the trunnion.

Side-tackle. A luff-tackle on either side of a broadside gun-carriage, having the inner-block hooked to an eye-bolt in the carriage, and the outer-block to the *fighting-bolt* or to the *securing-bolt* in the ship's side.

Side-tackle Block. These blocks are now made of gun-metal, with a *nib*, or half-hook, cast on them.

Side-tackle Bolt. The eye-bolt in the gun-carriage, to which the side-tackle hooks.

Siding. The breadth of a piece of a timber. Making two sides of a timber parallel.

Sight. An observation of the altitude or other angular distance of a heavenly body. A piece of metal fixed on a fire-arm for the purpose of directing the fire of the gun. The *breech-sight* is that placed at the breech of the gun, on which are marked the degrees of elevation and the distance corresponding to such elevation attained by the shot. The *front-sight* is a small wedge, placed farther towards the muzzle of the gun, which is so brought in line with the bottom of the notch in the breech-sight, and the object, that a straight line is formed by the line of sight. Sometimes this sight is on the muzzle; at others it becomes a *reinforce-sight*, when it is placed at or near the reinforce of the gun. *Side-sights* have been described above, and then the front-sight is a *trunnion-sight*, placed on the trunnion of the gun. *Tangent-sight*, see Tangent. *Dispart-sight*, see Dispart. Rifle-sights have a small side piece, allowing for the *drift* of the projectile. The fitting and adjusting of the sights of a gun is an operation requiring great care and precision. *Leaf-sights* are those on small-arms, where a movable leaf or hinge is raised, to obtain long ranges. *To sight*, to see, as *to sight land*. *To sight the anchor*, to heave it up to see if it is clear.

Sight-bar. A metal bar on which the range in yards, or in degrees, is marked. It is a part of the breech-sight, and, by raising or lowering it, different ranges are obtained.

Sight-cover. A metal cover, placed over the sight of a gun, to protect it from injury when not in use.

Sight-mass. A casting, or projection on the gun, on which the sights are placed.

Sight, Telescopic. Sights with telescopes attached, to magnify the object at great distances.

Sight-vane. See Vane.

Signals, Marine. Marine signals are certain signs agreed upon for suddenly communicating intelligence to distant objects at sea, to which the voice cannot possibly reach. The necessity for the establishment of a code of communication by means of fixed signs must have been made evident and have been provided for simultaneously with the first formation of a fleet for united action. It is well known that signals were made in the early Greek and Persian fleets by means of the sails, certain meanings being attached to the partial loosing of one or more. The exhibition of shields in prominent positions and flaming fires were also modes of communication. As the early naval tactics, however, comprised but few manœuvres, no full description of any single code of signals is to be found in ancient writings. Marine signal systems are properly divided into three main categories,—Day signals, Night signals, and Fog signals, and these branches will be treated of separately in considering the developments of the science.

Day Signals.—Of the systems coming under this head those involving the use of flags are the most important. That flag signals were in use as early as the 13th century is evidenced by one of the articles of the Laws of Oleron, by which it is prescribed that a vessel desiring a tow or a

pilot shall hoist her ensign. As early as the first part of the 17th century an approach to a regular flag code is noted, in which flags, pennants, and banners were used.

Papal Code (1614).—In the papal fleet instructions it is prescribed that: A pennant hoisted on the poop indicates "make sail," and it is to be dipped once for each sail to be set. A pennant from the mast-head look-out indicates a strange sail in sight; it is to be dipped once for each sail seen. A pennant from the yard-arm indicates that "wine is being served out to the crew." A square flag at the same place, "bread is being served out"; and both signals together, "bread and wine." A banner held up by a man standing amidships indicates "distress." A banner held up on the poop indicates "form line ahead." From these examples it is seen that both tactical and general signals were in use, and that a distinction of color in the flags was made at that day is evidenced by a fragment of fleet instructions issued as early as 1420 by the Venetian Capt.-Gen. Piero Mozenigo, in which it is stated that each galley of the fleet shall have a ship's signal, or, as it would now be called, a number, consisting of a pennant and a flag, which when hoisted should indicate that the admiral desired to communicate with such vessel. Although fleet signals were thus used, they appear to have been upon no fixed principles previous to the middle of the 17th century.

Duke of York's Code (1665).—To King James the Second of England, when, as Duke of York, he commanded the English fleet in the Dutch war of 1665, belongs the honor of first establishing a signal code upon a regular system. Exactly what this code was is not known, but it is surmised that it was based upon naming flags for the letters of the alphabet. It would seem scarcely probable that signals were spelled out by this means, as the majority of the commanders in his fleet in all probability were unable to read; but it is certain that his fleet instructions comprehended a long list of tactical and general signals based upon a regular system. By the middle of the 18th century this system had been developed to the extent that throughout the English fleet a code system was in use in which 30 flags were used, 1 for each letter of the alphabet and 4 auxiliary flags. This system was, however, quite complex, as different meanings were given to combinations when hoisted in different places.

Lord Howe's Code (1792).—In 1781 a Mr. McArthur, who had been secretary to Admiral Lord Hood on the American station, devised an improved code, which was introduced into the British service as Lord Howe's Code in 1792. In this code the number of flags was reduced to 13, and pennants were abolished. In the make-up of the flags 4 colors were used, Red, Blue, Yellow, and White,—there being but 2 colors in each flag. Each flag was known by a number from 1 to 12, and also by a letter. In designating the letters a very shrewd system was introduced. The flags were made as follows: In 3 the colors were horizontal; in 3 perpendicular; in 3 diagonal; in 3 double diagonal, and the 13th, called the "substitute" flag, was blue with a square white centre (the present blue peter). The flags taken in regular succession were called from the first 12 letters of the alphabet. For the next 12 they were inverted, or where inversion would make no change the *other color* was placed next to the mast. The last two letters were made with two flags. In this manner an alphabetical code was established, while for the numbered code, by means of the inversion and the substitute flag, 20,000 signals were made with not more than 4 flags in a hoist. It was by means of this system that the famous Trafalgar signal was made,—"England expects every man to do his duty." In this code also appears for the first time a division of the signal book into subjects,—Anchoring, Calling Officers, Chasing, Convoy, Fighting Instructions, Sailing Evolutions, Private Signals, and Miscellaneous.

United States Code (1795).—The early United States Code was almost precisely similar to the English development of King James's Code. There were 26 flags, one for each letter, and a number of pennants for special and defining signals. There was no fixed code dictionary, but beyond a few general signals each squadron commander made up his own combination. This continued until about 1816, when a code dictionary was issued, in which, however, no regular method was followed out. About 1826 the British Admiralty altered their system to a 10-flag code, introducing pennants again for defining the various meanings of certain combinations.

Rogers's American Code (1846).—The United States Navy Department adopted a code in 1846 devised by Henry J. Rogers, superintendent of telegraphs. In this code there were 9 square flags and 5 pennants. The flags were numbered from 1 to 9. One pennant was 0, or hoisted singly was the alphabetical signal. The next 3 were repeaters, and when hoisted singly were respectively, Answering, Yes and No. The fifth pennant was the "Numeral." The first 9 letters of the alphabet were made with the single flag, the next 9 by a square flag with a pennant under, and the last 8 by the square flag with the pennant over. The signals in the dictionary were numbered in regular order up to 13,405, the book being divided into 14 headings. In this system a pilot code was introduced for use in piloting ships into harbor or out when circumstances would forbid boarding. These were made by means of the union-jack hoisted in conjunction with one or more signals.

United States Code (1861).—Rogers's Code was modified in 1861 to a system having 12 square flags and 9 pennants; there being 10 numbered flags, 3 repeating pennants, and 2 square and 6 pennants as defining signals. The dictionary was reduced to contain 9999 signals. Thus this system was an elaboration rather than a modification of previous systems. In 1866 this system was still further elaborated by the addition of some 6 or 8 defining flags and pennants. At the same time the signal book was remodeled. Tactical signals were separated from the general signal book, and the latter was arranged according to the customary method,—Alphabetical, Compass, Word, Geographical, and General.

International Code (1856).—The British government devised a code for international use in 1856, which by 1871 had been adopted throughout the world with the single exception of the U. S. merchant marine. This code is made up of 1 burgee, or swallow-tailed flag, 13 square flags, and 5 pennants. Eighteen of these flags and pennants represent the 18 consonants of the al-

phabet, the nineteenth color being a pennant for answering and defining. In this code appears an arrangement that may well be called the perfection of principle. The signal book is divided into different topical headings, and it is the designation of these headings by which they may be known at great distances or in calms that constitute the excellence of the principle. The designations are as follows:

Two-flag signals having the burgee uppermost are attention signals.

Two-flag signals having a pennant uppermost are compass signals.

Two-flag signals having a square flag uppermost are urgent signals.

Three-flag signals are all general in character.

Four-flag signals having the burgee uppermost are geographical signals.

Four-flag signals having a pennant uppermost are spelling signals or names of men-of-war.

Four-flag signals having the square flag uppermost are names of merchant vessels.

This principle has been adopted in all naval codes except that of the United States, which at present is the most cumbersome extant.

Tide Signals.—At many ports where the rise and fall of the tide is very great, flag signals are used at some elevated shore-station to denote the depth of water in the channel at different tidal intervals. At these stations signals are also provided by which a ship may be directed in her course up the channel when circumstances forbid her being boarded by a pilot.

Storm Signals.—A system has been introduced along the coast of the United States, and is rapidly being extended to European coasts, by which the approach of a storm and the direction from which the wind will blow is signaled to departing or approaching vessels.

Distant Signals.—Under many circumstances it becomes impossible to communicate by means of flags during the day, and to obviate this difficulty a system of distant signals is introduced into the International Code. This system consists in substituting shapes to designate letters in place of flags; the objects chosen are a ball, a pennant, and a square flag, or objects which would approach these shapes, such as a bucket, an oar, and a shirt. Eighteen different combinations of these objects give the 18 consonants of the code. The same idea is carried out at shore-stations.

Semaphoric Signals.—At coast telegraph-stations semaphores are put up for communicating with vessels. These semaphores consist of a long staff having hinged at its top a disk, and down its length 3 long slats. The disk at horizontal means Answering, at vertical, International Code. A slat pointing angularly downward represents a pennant, horizontal, a ball, and angularly upward, a square flag. Thus any 3-flag signal (all such being general) may be made at one motion.

Night Signals.—The use of night signals probably originated about the same time as day codes; as previously noted, the ancients used signal-fires, and in Mozenigo's fleet instructions we find them provided for.

Mozenigo's Code (1420).—A fire exhibited on the poop shall signify "set the mainsail," 2 fires, "both the square-sails," 3 fires, "all plain sail," 4 fires, "lay in the oars and make all sail." In the papal prescriptions is found a reference to running lights: "Division and squadron commanders shall carry 3 lanterns at night, other galleys 1 lantern."

King James's Code (1665).—Guns were used for night signals soon after their introduction in naval services. King James instituted a regular numbered code, which, although appearing comical at this day, shows how wisely the principles of signaling were laid down at that time. In this code guns, blue-lights, and lanterns were used. One gun was attention, or number 0. Then 1, 2, 3, and 4 were designated by the corresponding number of lanterns, 5 by 1 blue-light, 6, 1 blue-light and 1 lantern, and so on up to 10, which was 2 guns. There were only 40 signals in the code, but the numbers were unmistakable. Thus, 39 would be 4 guns, 1 blue-light and 4 lanterns. The signals were all urgent or tactical.

Kempenfeldt's Code (1792).—The King James Code was used until the adoption of Lord Howe's Day Code, in 1792, when a code of lantern signals, devised by Admiral Kempenfeldt, and perfected by Mr. McArthur, was adopted. This code did away with guns and blue-lights, using only lanterns. Eight lanterns were used, divided into 2 groups; 4 were hoisted either at the starboard yard-arm or fore-gaff, and 4 at the port yard-arm or spanker-gaff, depending upon the position of the vessel signaled to. Each lantern was provided with a tin "obscurer," worked by tricing lines from deck, and numbers were signaled by means of the combinations of two or more lights shown. Whilst this system was used, the old gun and light method was retained for important fleet signals.

Rogers's Code (1846).—Colored lights were introduced for signal purposes in the first part of the present century, but the first regular pyrotechnical system was devised in the United States by Rogers. In this system, pyrotechnical composition was made up in small cylinders, colors corresponding with the day flags. By removing a small cap and igniting the composition with a slow-match, the colors burned in regular succession.

Coston's Code (1858).—The Rogers system was modified and improved in 1858, by Gunner Coston, of the U. S. navy. A more brilliant composition was introduced, and the signals were so made that they were held in the hand and ignited by percussion.

Very's Code (1877).—Lieut. Very introduced a code in 1877, in which a departure was made from Rogers's principle. The signals themselves were devised on the principle of a ball cartridge, single stars being shot into the air to a height of about 400 feet. The principle of the code approached closely that of a telegraphic system. Each digital number or letter of the alphabet is made by the same number of stars, so that in transmitting a signal no time interval is made between letters or figures. By a simple method of interjecting stars in the regular course of a signal, the desired message is so completely ciphered as to be entirely unintelligible to any except those understanding the cipher. In place of the 18 or 20 different pyrotechnical pieces used in the Rogers and Coston codes, but 2 are used, and only 2 colors, in place of the 3 of the earlier methods.

Rule of the Road Signals.—It has been stated

that running lights were used regularly as early as the 15th century, and probably they were used much earlier, but no change in the method of carrying a light at night appears to have been made from the earliest days down to 1846, when it was prescribed that steamers should carry 2 lights. In 1852 the rule for vessels to carry a red light on the port side, and a green light on the starboard side, was adopted. In 1861 steamers were ordered to carry a white mast-head light. In 1864 the international rules were promulgated, by which sailing-vessels, steamers, vessels in tow, and pilot vessels were made distinguishable by their lights. In 1880 these rules were revised, and additional lights were provided for vessels in distress, and for vessels engaged in different kinds of fishing.

Fog Signals.—The custom of blowing fish-horns to denote the position of a vessel in a fog is one several centuries old, but no regular rules for fog signals appear to have been made previous to about 1840, when the rule for sailing-vessels of blowing 1 blast when on the starboard tack, 2 on the port, and 3 when running free, was made. About this time the rule for steam-vessels to blow the whistle was established. In 1864 fog signals were incorporated in the Rules of the Road, the old rule for sailing-vessels being abolished, and in place of it a single signal of 1 blast introduced. All vessels at anchor in a fog struck the bell at short intervals, in place of sounding a horn or whistle. In 1868 a rule was adopted in United States waters by which, at all times, when a steam-vessel changed her course to avoid another, she blew 1 short blast if keeping to starboard, 2 if keeping to port, and 3 if backing. In 1880 the new Rules of the Road made the system complete. By these rules steamers blow 1 long blast at intervals in a fog, 1 short blast if keeping to starboard, 2 if keeping to port, and 3 if backing. Sail-vessels blow a mechanical horn; 1 blast for the starboard tack, 2 for the port tack, and 3 for running free. Vessels at anchor toll the bell at short intervals.

Course Signals.—In addition to the above-mentioned fog signals, various propositions have at times been submitted to different governments for the introduction of a code of signals that should designate the course a vessel is heading in a fog. One system has been adopted in Sweden, and that government is at present making endeavors to have it made general.

Ahlborg's Code.—In this code 2 whistles are used,—a shrill treble and a deep bass. North is denoted by a blast of the treble whistle. N. E., one treble and one bass. E., one treble and two bass. S. E., one treble and three bass. S., one bass. S. W., one bass and one treble. W., one bass and two treble. N. W., one bass and three treble.

Telegraphic Signals.—The first military code of telegraphic signals of which well-authenticated information exists was devised in France, in 1793. This consisted of a semaphore, having two pivoted and jointed arms, by which combinations representing letters of the alphabet could be readily made. This system was adopted in the French navy, and was shortly afterward introduced into the British navy in a modified form. A system upon the same basis was introduced in the U. S. navy about 1830. The principles of this system are used at present in European navies; but in that of the United States, the semaphoric method has been replaced by Myer's code, consisting of combinations of two elements, expressing the letters of the alphabet. This system is transmitted by day by means of swinging flags, and at night by swinging lanterns.—*Edward W. Very, Lieutenant U.S.N.*

SIGNAL-BOOK. A book in which signals are recorded. A book containing the code of signals. Signal-books are bound with metal, so as to sink in case of capture, and are kept in the cabin.

SIGNAL-CHEST. A chest on the poop, arranged with pigeon-holes for signal-flags.

SIGNAL-FLAGS. The flags used in signaling.

SIGNAL-LOCKER. A locker to contain signal-flags.

SIGNAL-MAN. A man who makes and reads signals.

SIGNAL-OFFICER. The officer charged with the supervision of signals.

SIGNAL-QUARTERMASTER. A petty officer who has charge of the signals, lights, lanterns, etc.

SIGNALIZE. To make signals to.

Signing-officers (*Eng.*). Officers accountable for stores, who sign the receipt therefor.

Signs of the Ecliptic, or Zodiac. The ecliptic is divided into twelve equal portions called *signs*, each occupying 30° of its circumference, commencing from the vernal equinoctial point, or first point of Aries. The names of the signs, in order, with their several symbols, are as follows: *Aries*, ♈, *Taurus*, ♉, *Gemini*, ♊, *Cancer*, ♋, *Leo*, ♌, *Virgo*, ♍; *Libra* ♎, *Scorpio* ♏, *Sagittarius* ♐, *Capricornus* ♑, *Aquarius* ♒, *Pisces* ♓. The first six are the northern, and the last six the southern signs. These are the names also of the twelve *constellations* of the zodiac; and when this notation was established, "the signs of the ecliptic," or, as they are sometimes called, "the signs of the zodiac," coincided in position with the "constellations" of the same name, which name, consequently, the sign took. This coincidence, however, no longer exists. The vernal equinoctial point, or first point of Aries, from which the divisions of the ecliptic commence, has a slow retrograde motion along the ecliptic, so that it is no longer in the constellation of Aries, but is now situated in that of Pisces, and so for all the "signs" whose position is defined by that of the origin; they have retrograded with respect to the corresponding constellations, or, which is the same thing, the constellations have progressed relatively to them, the constellation Aries now occupying the sign Taurus, the constellation Taurus the sign Gemini, and so on. Hence it must be particularly observed that the signs of the ecliptic are now regarded as purely technical subdivisions, and are not to be confused with the constellations of the same name, though they were originally identical. In former times it was usual to note the longitude of a heavenly body in *signs*, *degrees*, *minutes*, and *seconds*, a sign being equal to 30°.

Silence! A command to the men at the guns, when they all face the gun, and await in silence further orders.

Sill. A young herring. The timber at the base of a dock-entrance, against which the gate shuts. The upper and lower part of the frame of a port.

Sillock (*Eng.*). Young coal-fish.

Silometer. A speed measurer; a log towed in the wake of the ship, registering the speed. See Log.

Silt. Soft, oozy sediment. *To silt up*, to become choked up with mud or sediment.

SILT-GROUNDS. Deep-water fishing banks off Jamaica.

Siluridan. A fish of the family of which the genus *Siluris* is the type.

Siluris. A genus of large malacopterygious fishes, without true scales, and found in the inland waters of Europe, Asia Minor, etc.

Silver-fish. A fish of the size of a small carp, having a white color, striped with silver lines.

Silver-oar (*Eng.*). A badge of a maritime court.

Silver-thaw. The ice falling in large flakes from sails and rigging.

Simoom. A hot, dry wind, blowing from the Arabian deserts.

Simpson, Edward, Commodore U.S.N. Born in New York. Appointed from New York, February 11, 1840; attached to sloop "Decatur" and frigate "Potomac," Brazil Squadron, 1840–41; returned to the United States in frigate "Constitution," 1841; attached to frigate "Independence," Home Squadron, 1841–42; attached to frigate "Congress," Mediterranean and Brazil Squadrons, 1842–45; attached to receiving-ship "North Carolina," 1845; Naval Academy, Annapolis, Md., 1845–46.

Promoted to passed midshipman, July 11, 1846; war with Mexico; attached to steamer "Vixen," 1846–47; present at attack on forts of Alvarado, under Commodore Connor; at two attacks on Tabasco, under Commodore Perry; at capture of Tampico, under Commodore Perry; at capture of Tuspan; at capture of Coatzacoalcos; at capture of Laguna de Terminos. At siege of Vera Cruz, covered the landing of the U. S. army, and took part with the rest of the Mosquito Fleet in the bombardment of the city of Vera Cruz and of the Castle of San Juan de Ulloa; attached to coast survey, 1848–50; attached to frigate "Congress," Brazil Squadron, 1850–53; attached to Naval Academy, as assistant instructor in naval gunnery and infantry tactics, 1853–54.

Promoted to master, July 10, 1854; coast survey, 1855–56.

Commissioned as lieutenant, April 18, 1855; attached to sloop "Portsmouth," East India Squadron, 1856–58; engaged with Commander A. H. Foote in the bombardment and capture of the Barrier Forts in the Canton River; attached to Naval Academy, in charge of instruction in theory and practice of naval gunnery, 1858–62; commandant of midshipmen, at Naval Academy, 1862–63.

Commissioned as lieutenant-commander, July 16, 1862; commanding ironclad "Passaic," South Atlantic Squadron, 1863–64; engaged with Fort Wagner, July 29, 1863; Fort Sumter, August 17, 1863; Fort Wagner, August 18, 1863; Fort Sumter, August 23, 1863; Fort Moultrie, August 31, 1863; Fort Sumter, September 1, 1863; Battery Bee, September 8, 1863; Fort Moultrie, November 16, 1863; commanding steamer "Isonomia," off Wilmington, in East Gulf Squadron, and on Bahama Banks, 1864; fleet-captain, Blockading Squadron, 1865–66; engaged in operations before Mobile, from March 27, 1865, to April 12, 1865, when the city capitulated.

Commissioned as commander, March 3, 1865; commanding steam-sloop "Mohican" and steamer "Mohongo," North Pacific Squadron, 1866-68; in charge Hydrographic Office, Washington, 1868–69; assistant to chief of Bureau of Ordnance, Navy Department, Washington, 1869–70.

Commissioned as captain, August 15, 1870; special service in Europe, 1870–72; commanding Torpedo Station, 1873; commanding steam-frigate "Franklin," North Atlantic Station, 1873–74; commanding frigate "Wabash," North Atlantic Station, 1874; commanding Torpedo Station, 1874–75; commanding steam-sloop "Omaha," South Pacific Station, 1875–77; navy-yard, New York, 1877–78.

Promoted to commodore, April 26, 1878; commandant Naval Station, New London, Conn., 1878–80.

Sing. To cry out in hauling on ropes,—not tolerated in the navy. *To sing out*, to cry out.

Single. To unreeve the parts of a doubled rope, as tacks and sheets.

Single-acting Engine. An engine in which the steam acts on one side of the piston only.

Single Anchor. A ship is at a single anchor when only one anchor is down.

Single-banked. When but one man on a seat rows a single oar, a boat is said to be *single-banked*. Gigs, dingeys, and whaleboats are single-banked.

Single-block. A block with but one sheave.

Singlestick. A wooden sword, used in broadsword exercise.

Sinical Quadrant. An instrument formerly used to work out traverses.

Sinking-head. An extra length on a casting, into which the poorer metal sinks, and is cut away. Also called *sprue-head*.

Sinnet. See SENNIT.

Sirius, or Dog-star (Gr. *Seirios*, from *seirein*, to scorch). The bright star *α Canis Majoris* is so called for the following reason: In ancient times the heliacal rising of this star followed close upon the summer solstice. This, in the Mediterranean latitudes, was the season of the greatest heats, unhealthy and oppressive, and during which dogs were liable to madness. The Egyptians called this star *Sothis*, and from its heliacal rising were warned that the annual overflow of the Nile was about to commence. Owing to the precession of the equinoxes the heliacal rising of Sirius has slowly changed; it takes place now about August 10.

Sirmarks. Stations marked upon the molds for the frame-timber, etc., indicating where the bevelings are to be applied.

Sirocco. A hot and dry wind, southeast in Italy, blowing from the desert.

Sissoo. A kind of Indian ship-timber.

Sister-block. A double-block, having one sheave over the other, the shell being in one piece. It is seized in between the two forward topmast shrouds.

Sister-hooks. A pair of hooks, working on the same axis, and closing into one, fitting closely in that position.

Sister-keelsons. A pair of keelsons placed on each side of the middle line.

Sister-ships. Ships made on the same model, and rigged alike.

Sitch. A little stream of water, dry in summer.

Six-upon-four (*Eng.*). Rations reduced at the rate of 6 to 4 men.

Six-water-grog (*Eng.*). Grog weakened to six parts of water, for punishment.

Size-fish. A large whale, whose whalebones are at least 6 feet long.

Sizing. A gelatinous solution used in painting, gilding, etc.

Skate. A cartilaginous fish of the genus *Raia*, having the body flattened, the skin set above with spines or thorns, the branchial openings below, and cartilaginous flaps extending from the nose backward toward the pectoral fins, which last form broad, lateral expansions, and give the whole body a rhomboid form. It is wholly marine, and is found in all parts of the world. The *Raia batis*, called the *skate*, *gray skate*, or *blue skate*, weighs sometimes 200 pounds, and is used for the table.

Skate-lurker. Cant for a begging impostor in sailor-clothes.

Skeat. The star *β Pegasi.* See PEGASUS.

Skeel. A wooden bucket, or water-kid.

Skeer. See SCAR.

Skeet. A long-handled scoop, used to wash the sides of a ship, and formerly, to wet the sails.

Skee-tack. A name for the cuttle-fish.

Skeg, or Skegg. A projecting stump formerly left on the keel, abaft the stern-post. The after-end of the keel. The composition piece supporting the heel of an equipoise rudder.

SKEGG-SHORES. A name for the shores under the after part of the keel, when launching a ship.

Sker, or Skerry. A flat rock, always above water.

Sketching. The art of sketching is of the greatest practical utility to the naval officer, and in every branch of his profession an ample field is afforded for the exercise of this accomplishment.

Most of the popular and scientific magazines and journals are filled with skillful reproductions of pen or pencil sketches, and indeed a descriptive article is hardly considered complete without these embellishments.

The intimate relation of drawing to almost every art and trade is generally recognized, and in the principal countries of Europe the instruction of artisans in the uses of pen, pencil, and brush is encouraged by the government.

It is not presumed that one should necessarily be an accomplished artist in order to produce very useful and creditable plans and sketches. Enough for practical purposes can be done by any intelligent person who will devote a reasonable amount of time to acquiring a few rudimentary principles and sufficient practice.

Whatever may be the advantages of the camera, that valuable instrument is not always at hand, and when it is, circumstances beyond our control often prevent its use; this is especially apt to be the case at sea.

In time of peace many of our naval officers will be employed in surveying, and on squadron service no officer is more usefully engaged than when collecting and transmitting the information which his surroundings afford. Designs of the novel vessels now building in Europe, fortifications, breakwaters, landmarks, approaches to harbors, and new inventions in artillery can in no way be so clearly and accurately described as by sketches.

In time of war there can be no question about the advantages of an art which is capable of presenting at a glance the order of battle, plan of attack and defense, positions of fortifications and obstructions, and the manifold considerations that must influence the movements of a commander.

The report of the Honorable Secretary of the Navy for 1879 is an example of the Department's encouragement and appreciation of such efforts. Our text-books on seamanship and gunnery teem with illustrations, and every inventor, to present clearly his ideas, must be aided by sketches and plans.

To the marine surveyor the art is invaluable. An officer who has seriously tried to sketch during the progress of a survey will often be gratified, if not surprised, at the amount of information which even very crude sketches may afford. The pencil is of course the chief instrument for such delineations,—a hard one is best, and drawing-blocks or sheets of paper are necessary. With these simple appliances the boat-officer will be able to sketch in the coast-line, while from the ship the more general outlines of the country surveyed may be drawn. Such work will probably represent only a rough outline, stained by the salt spray and very "shaky" in execution, but if it be neatly copied in the sketch-book before the scene is forgotten, minor details may be supplied, and the purpose is accomplished. Circumstances rarely admit of the selection of positions for pictorial effect, but there are certain essentials which should if possible be complied with.

The main object is the selection of a station, or point of view, the distance of which from the scene or object should not be less than the width of the latter,—in many cases it may be greater,—but where the distance equals the width of the scene, the angle of vision will not be much less than 60°, which is the greatest the eye can take in at one view. Having determined on and occupied this position, and chosen the objects that are to constitute the front of the picture, the paper having been previously cut nearly the size of the intended drawing, the delineator holds it up with his left hand before the scene, its lower edge corresponding with the front line of those objects, at such distance from his eye that the width may exactly comprise the scene to be drawn. With the paper in this position let him first mark on both its sides the exact intersections of the horizon which connect by a line across it, opposite to this mark the point of sight. On the sides and upper and lower edges mark the places, the heights and widths of the principal lines and objects.

With the assistance of these marks and the point of sight, and frequent careful references to the scene, the objects may be drawn in their proper places and in tolerably good perspective, which may afterward be verified and corrected by rule. The thickness and force of the various marks and lines must be graded to the distance of the objects they respectively represent. In sketching, this is a great aid to perspective effect; and by beginning first the distance with a finely-

pointed pencil, the marks, as they approach the foreground, will of themselves acquire increased thickness by the wearing down of the point. Care must be taken to avoid too many marks and lines, which will produce a confused effect, and is a common error with beginners, who should study to attain the smallest number of marks that will correctly denote the character of the object. Increased boldness in the outlines of the foreground may be produced by using a softer and blacker pencil; this will often assist the perspective effect by increasing the idea of their nearness to the spectator.

These are the main points to be attended to in a sketch from nature, so far as perspective is concerned. The character of details, such as the representation of kinds of foliage, should vary according to the distance, which will, in some degree, assist the perspective idea of distance. No precise directions can be laid down for the representation of the objects of nature; almost every artist has a way or *touch* of his own by which he conveys his ideas, and this is best acquired by a contemplation of the objects themselves and studies of the works of the best masters.

The proper management of *light and shade*, and their judicious arrangement into breadths and masses, called by painters *chiaro-oscuro*, are also valuable aids to the perspective effect of a landscape. It is a common mistake with the novice to appropriate to each individual tree, figure, house, or other object its own light and shade, irrespective of the general effect. The consequence is that the picture is cut up into a great number of lights and shadows of nearly equal size and intensity, alternating over the entire surface of the picture, by which means the eye is distracted, and cannot rest with satisfaction on any portion of it, since all the objects depicted are thus made to present nearly equal claims to attention. The avoidance of too many lights, the placing of the principal object in one larger and more intensely illuminated space, the keeping of other lights subordinate to it, and the proper regulation of the contrasts between light and shadow, according to distance, all tend to direct attention to the principal object, and to preserve the proper *keeping* of the picture. The same may be said of the shadows. There should be one principal shadow, to which the others should be subordinate; they should not be too much subdivided into numerous small shadows, but a proper degree of breadth of shade should be maintained undisturbed by intervening lights, which will much contribute to the repose of the picture.

Every landscape may be divided with greater or less precision into three parts,—the distance, the middle-picture, and the foreground. As the effect of distance is to subdue both lights and shadows, the first of these seldom plays a conspicuous part in the general arrangement of the *chiaro-oscuro*, although the deep blue of a distant mountain in full shadow is sometimes effectively introduced. The largest breadth of shade is generally spread over the middle-picture, while the deepest shadows, as well as the strongest lights, naturally, from its proximity, occupy the foreground.

Sometimes, however, this order is reversed. In this case a few strong and scattered touches of light falling on objects in the foreground contrast very effectively with its dark tints. In daylight scenes, in nature, the principal light is generally in the sky; but in a showery or stormy sky, when the sun is supposed to be shining, but not from within the limits of the picture, the entire sky may often be in half-shadow, with the principal light in the foreground or middle-picture.*

Guided by these simple instructions, it is supposed that a sketch of a harbor, bay, or island has been made in pencil. To render such work more permanent and give a greater effect the sketch may be finished in India-ink, sepia, or water-colors by the aid of the pen or brush. Pen and ink are chosen for our present purpose as being best adapted for photolithography and the most simple. A photograph may be taken directly from such a sketch, and to obtain the best results it is necessary to pay particular attention to clearness, and draw the picture a little larger than required in the published sketch.

The ink used should be of the best quality, free from hardness and grit, and susceptible of a deep, brilliant, black tint when sufficiently ground on the saucer. Distilled water is preferable for grinding, and if the sketch is to be photographed a little alum may be mixed with the ink, which will neutralize its brilliancy. If flies are troublesome, a small quantity of ox-gall added to the ink will prevent the sketch being spoiled by their encroachments. For very fine work the ink may be ground to advantage on the thumb-nail. The saucer should be thoroughly cleaned and wiped before and after use; any particle of grease destroys the fixing and fluid qualities of the ink.

Hot-pressed drawing-paper or Bristol-board is the best to use for such sketches. The pens best adapted for free-hand work are Gillott's No. 303, the mapping-pen, No. 291, and the lithographic pen, No. 290; with these grades all delineations from the finest to the coarsest may be made, but in skillful hands the 303 pen, like the *moyen* pencil, suffices for all ordinary purposes. The character of the pencil-lines should be accurately rendered by similar touches of the pen and tints of ink.

The amount of finish necessary to the sketch depends upon the time and facilities at the disposal of the delineator. In general, on shipboard, it is not convenient to be too minute; the refinements may be left for office-work, where good light, steadiness of position, and command of the best materials will conduce to greater neatness and accuracy.

English surveying-vessels are usually provided with a large, airy, well-lighted house on the upper deck devoted exclusively to the use of the surveyors and draughtsmen.

An important point not to be omitted in the sketch is reference to the point of view by bearings, which should be carefully noted.

The best time for making sketches is either in the morning or evening, when the effects of light and shade are most favorable.—*George P. Colvocoresses, Lieutenant U.S.N.*

Skew. Awry. A rudely-made boat in English waters.

Skewer-pieces. Pieces of salt meat without bone.

* I am largely indebted to a manual of drawing by R. S. Burn, Esq., for the foregoing directions.

Skiddy-cock (*Eng.*). The *water-rail.*

Skider (*Eng.*). The *skate.*

Skids. Pieces of timber temporarily fastened to the rail or side, to absorb the chafe in hoisting. Pieces of plank under a vessel's bottom for getting her afloat, when ashore. *Boat-skids* are frames in which boats are built, or in which the boom-boats rest. *Landing-skids* are short pieces of plank running from the gunwale to the beach, and are used in boats, for the purpose of landing the guns. *Gun-skids* are beams arranged in parallel lines, in a gun-park, on which the guns are laid.

SKID-BEAMS (*Eng.*). Beams raised on stanchions on the spar-deck of a sloop, where booms and boats are stowed.

Skiff. A small light row-boat. (*Eng.*) A sail-boat like a sloop, but with no bowsprit.

Skilly. Oatmeal broth in which meat has been boiled.

Skillygalee. A drink of oatmeal and water.

Skin. The inside or outside planking of a ship. The outside part of a sail when furled. *To skin up a sail*, to pull it up in furling until the outside part is taut and smooth.

Skip-jack. A fussy, trifling officer; an upstart. The *bonita*, a small fish. A small porpoise.

Skipper. The master of a merchant vessel. A familiar appellation for the commanding officer of a man-of-war. The saury-pike, *Scombresox saurus.*

Skirling. Small salmon or trout.

Skiver. A dirk. A fork.

Skoorie. A full-grown coal-fish.

Skout. The guillemot, or auk.

Skouther. The stinging-nettle, or jelly-fish.

Skow. See Scow.

Skrae-fish (*Eng.*). Fish sun-dried without salting.

Skua. A kind of sea-gull.

Skulker. A shirker; a coward who lurks below during action.

Skull-fish. A whale more than two years old.

Skunk-head. The pied duck, *Anas Labradora.*

Skurrie. The shag, *Phalacrocorax graculus.*

Sky-gazer. A fish called *Uranoscopus.* A light triangular sail, set flying above the royal.

Skylarking. Frolicking; scuffling or running about decks. It formerly meant mounting to the mast-head, and sliding down the royal backstays.

Skylight. A hatch covered with glass, admitting light to the deck below.

Sky-sail. The next sail above the royal. Often carried in merchantmen, and sometimes set flying. The sail above it was the sky-scraper, if triangular; the moon-sail, if square.

SKY-SAIL MAST, or SKY-SAIL POLE. The upper portion of a royal mast when used for a sky-sail. Sometimes it slides on the royal mast, like a *sliding-gunter.*

Sky-scraper. A triangular sail set above the sky-sail, or above the moon-sail, when it is often called a *star-gazer.*

Slab. The outside cut of a tree.

Slab-lines. Ropes led through blocks on the yard or under the top, and thence abaft to the foot of the courses. Their use is to haul the sail up snugly.

Slack. A *slack rope*, one hanging loose. The *slack*, the loose part of the rope. *To slack off*, to ease up, or relieve the strain on a rope. *Slack helm*, with the helm carried habitually too much alee. This occurs often when too much down by the stern, or when there is too much head-sail. *Slack in stays*, a term applied to a ship that is slow in tacking; also, jocularly, to a lazy man. *To slack up*, to ease off or veer out. *Slack-tide*, or *slack-water*, the interval between ebb and flow, either at high- or low-water. *The tide slackens* when its velocity becomes less.

Slag. A glass-like substance formed in a blast-furnace by the combination of the silica, alumina, lime, etc., contained in the ore and flux. It floats, in a molten state, upon the surface of the metal, from which it flows through suitable apertures.

Slake. Mud or ooze in a river-bed.

Slant of Wind. A temporary breeze; also, the duration of a favorable breeze.

Slant Tack. The most favorable tack; the *long leg.*

Slatch. A transitory breeze.

Slee. A cradle placed beneath a ship when hauling her up for repairs, as at a marine railway.

Sleep. A sail *sleeps* when well filled and quiet.

Sleeper. A large acanthropterygious fish of the family *Gobiodæ*, the species of which are natives of warm climates, living in fresh water, and concealing themselves in the mud; *Eleotris dormatrix.*

Sleepers. Pieces of curved timber which are fayed and bolted upon the transoms and counter-timbers inside the ship to strengthen the stern. The lower tier of casks.

Sleeve. A strait, or narrow channel.

Sleeve-fish. The squid, *Loligo vulgaris.*

Slice. A bar used by whalers, to strip fish with. A tapering piece of plank, driven between the timbers of a ship before planking. A wedge driven under the keel in launching.

Slice-bar. A bar with a knife-shaped end, used in furnaces to clear the grate of clinkers.

Slide. A smooth piece, or a part of the frame of a machine, upon which another piece slides or is guided; as, the *cross-head slide* of a steam-engine, the *slide* of a gun-carriage, etc.

SLIDE-BAR, or SLIDE-ROD. A bar or rod for communicating motion from one piece to another, constrained by guides so as to move or *slide* in direction of its length only.

SLIDE-VALVE. A valve that is opened or closed by sliding it over its seat, which contains ports or openings, usually rectangular in cross-section, for the passage of a fluid. It is extensively used in the steam-engine for alternately admitting and releasing the steam to and from the cylinder; and for this purpose it is so arranged that one reciprocating piece performs these functions for both ends thereof. The simplest form is the *three-ported valve*, in which the valve-seat contains three rectangular ports, placed side by side a short distance apart, the two outer ones communicating with their respective ends of the cylinder, and the middle one with the exhaust-pipe. The valve, in the middle of whose face is a niche or recess of sufficient size to span the middle port and one of the end ports, when in mid-position and the engine on a dead centre, covers all the ports; but when

moved in either direction, one of the end ports is uncovered to the live steam surrounding the back of the valve, the other releasing the exhaust steam through the niche in the valve-face and the middle port. Slide-valves having *lap* are enabled to effect a *cut-off* within moderate limits. *Double-ported* valves have two steam and exhaust openings at each end, thereby reducing the length of their stroke. There are many devices for relieving the bases of valves from the steam-pressure, such as the *D-valve*, the use of *balance-rings*, etc.

SLIDING-BAULKS. The floor-timbers of a cradle, sliding on the bilge-ways when the ship is launched.

SLIDING BILGE-BLOCKS. Large blocks with their upper parts fitted to the form of the ship's bottom, sliding from the dock-steps into place.

SLIDING-GUNTER. A mast of two pieces, the upper sliding up and down the lower by means of hoops or rings. Used for boats, and sometimes for sky-sails, etc.

SLIDING-GUNTER SAIL. A triangular sail bent to a sliding-gunter mast. A handy form of boat's sail, reefing quickly by lowering the upper part of the mast.

SLIDING-KEEL. A sliding-keel or centre-board is an arrangement invented about the year 1800 by Capt. John Shanks, R.N. It consists of a well-room or case placed amidships, and carried above the deepest load-line, generally to the deck. It contains a board made to travel up and down, as the vessel may be required to sail off or on the wind; it is used principally in yachts and coasters where a light draft of water is needed. Shuldham's sliding-keel was triangular, the broadest part being aft.

SLIDING-WAYS. Sliding-ways, or launching-ways, are the ways which are prepared for and used in launching a vessel; they are placed at an inclination sufficient to allow the ship to slide gradually into the water.

Sling. To suspend in ropes. To hang the yards with spare chains on going into action. To attach the clews to a hammock. A rope or chain strap fitted to encircle any object, so as to suspend it. The chains that suspend the lower yards and gaffs. *Yard-slings* are of strong chain, going around the lower mast-head, and connecting to the yard by a slip-bolt. *Gaff-slings* are of chain or wire rope, supporting the gaff from above. *Boat-slings* are lengths of chain terminated by a large link, placed in the bow and stern of the boat to hook the tackles into. *Buoy-slings* are rope fittings about a wooden buoy, to which the buoy-rope is so attached that the buoy will ride upright. *Butt-slings*, or *barrel-slings*, are used in hoisting casks. *Gun-slings* are iron chains parceled and marled together for a part of their length, and having a piece of rope fastened to them to pass about the chase of the gun. *To get into a sling*, a jocular expression, signifying to get into difficulties.

SLING-BAND, or SLING-HOOP. An iron band on the yard, to which the slings are fastened.

Slip. To let go suddenly; as, to *slip* the cable. An inclined plane on which ships are built. An opening left between docks or wharves. An inclined plane, up which ships may be drawn for repairs. An insurance memorandum, given to the underwriters for their signatures. The difference between a vessel's speed and the speed that would be attained if the propelling device acted upon a solid or immobile substance instead of a fluid. It is usually expressed as a fraction or *per centum* of the speed due to the action of the centre of effort of the propeller on a solid.

SLIP-KNOT, or SLIP-NOOSE. A knot which will travel along a rope or spar; a running-noose.

SLIP-ROPE. A rope so arranged that it may be slipped or let go suddenly.

SLIP-SHACKLE. A shackle consisting of a long bolt with a ring, confining it to its own part, and, when struck off, allowing it to slide through the chain to which it is fastened.

SLIP-STOPPER. An arrangement for letting the anchor go. Usually, the ends of the anchor-stoppers have a tongue held in a *trip*, which is held by a trigger and controlled by a line, so that one man may detach both stoppers.

Sloop. A small vessel having one mast, with a jib, stay-sail, mainsail, and gaff topsail. It differs from a cutter in having a fixed bowsprit and stay for the jib. A war-vessel next in size to a frigate. Before the introduction of steam, a sloop-of-war carried from 18 to 32 guns. As now understood, any vessel, larger than a gunboat, carrying guns on one deck only.

SLOOP-RIGGED. Rigged like a sloop, with one mast and a fixed bowsprit.

Slope of Wind. A slant of wind.

Slops (*Eng.*). Ready-made clothes and other furnishings for seamen.

SLOP-BOOK. A register of small stores issued.

SLOP-ROOM. The issuing-room, or store-room for small stores.

SLOP-SHOP. A shop where sailors' ready-made clothing, small stores, etc., are sold.

Slow-match. See MATCH.

Sludge. Thin, slushy ice, just forming. Broken ice in polar seas.

Sludge-holes (*Eng.*). Mud-holes of boilers.

Slue. To turn around; to twist about.

SLUED. Stupefied by drink; tipsy.

SLUE-ROPE. A rope for turning a gun, spar, etc.

Slush. The melted grease from the meat in the coppers. Dirty snow, soft mud, etc. To grease with slush. *To slush down*, to grease the spars after scraping them.

SLUSH-FUND. Money obtained from the sale of slush. It is to be used for premiums for target firing, etc., and not for ship's purposes.

SLUSH-ICE. The first young ice.

Sly-gorse. The shell-drake, *Tadorna vulpanser*.

Smack. A small vessel, rigged like a cutter or a sloop, sometimes with a square topsail.

Small. The small part of a whale's tail. The shank of the anchor, immediately below the stock.

Small-arms. Fire-arms, carried in the hand, and fired from the hand or shoulder.

SMALL-ARM AMMUNITION. Ammunition for rifles, pistols, etc. It is generally *fixed ammunition*, and is stowed in boxes, kept in the shell-room or torpedo-room. Metallic cartridges are now used.

SMALL-ARM MEN. Men trained and selected to use small-arms in boarding, etc.

Small Bower. Formerly, the bower-anchors were of different sizes, in which case the port anchor was the *small bower*.

Small Helm. That condition of the steerage of a ship when but a slight movement of the helm is required to accomplish good results. The subjection of a talkative, turbulent bully by decisive measures.

Small Sails. All the lighter sails except the studding-sails.

Small Stores. Soap, needles and thread, tobacco, spices, tin-ware, razors, brushes, and various other articles, issued to the men through their mess-cooks once a fortnight.

Small-stuff. The general name given to all of the smaller descriptions of rope or cord which is required for use on shipboard.

The term includes spun-yarn, marline, houseline, roundline, and the smaller sizes of seizing- and ratline-stuff (all of which are made of hemp and tarred), and the corresponding sizes of untarred line, made either of flax or manilla.

In the manufacture of all these varieties, the finest quality of fibre is or should be used, except for spun-yarn, which is of a coarser description and requires less strength and finish. The long fibre of the tow, called *barr*, is generally used for that purpose.

Spun-yarn, marline, houseline, and roundline are made by the process of hand-spinning, as follows: at each end of the spinning-room, which is several hundred feet in length, wheels are placed which are turned by hand, and connect by means of bands with several small hooks or *whirls* supported in an open box. The spinner secures a bundle of hemp about his waist with the ends fastened behind, attaches a small quantity of the fibre to one of the whirls, which is revolved by the wheel, and walks backward the length of the room, by which movement the fibre is drawn from the bundle.

The thread or yarn is held in the right hand of the spinner (a piece of flannel being used to protect the hand from friction), the thumb and forefinger serving as a gauge to regulate the size and uniformity of the yarn, while the supply is regulated by the left hand, either faster or slower as may be required. The requisite amount of skill to spin a uniform yarn of a given size can only be obtained by long practice, but by a good workman a yarn of greater evenness and strength can be spun by hand than by machinery.

Upright posts placed in the floor at regular intervals have horizontal arms attached at right angles to the walk of the spinner, which are called *stake-heads.* Iron pins or bolts are driven into the upper edges of the stake-heads and hold the yarns in position, as the spinner, in passing, places the yarn upon it.

Two or three spinners follow each other at intervals of a few feet. Having reached the end of the room, a bell is rung as a signal to stop the wheel, and the ends of two yarns are knotted together and the bight placed over a hook. At the same time the man who turns the wheel detaches the yarns from the whirls, secures them to another whirl which is turned in the opposite direction by the crossing of its band, and by which the yarns are twisted together or laid up. A bundle of the completed lengths is called a *junk*, the number of which it is composed depending upon the weight.

Yarns for spun-yarn, marline, and houseline are spun from left to right, and are twisted or laid from right to left. Yarns for roundline are spun in the opposite direction and laid up *right-handed.* Spun-yarn may be made of two, three, or four yarns. They are simply twisted together, but not laid. It is used for the more common and rougher purposes, such as for service to protect certain parts of the rigging from chafe, bending sails, etc.

Roundline, houseline, and marline are made with greater care, and in laying the yarns a *top* is used to give closeness and regularity to the lay. The latter is composed of two yarns or strands; the others have three yarns, but roundline is somewhat larger than houseline, and is used principally in serving the lower rigging and stays. All of these different kinds of small-stuff are tarred in the junk.

The different sizes of ratline- and seizing-stuff are distinguished by the number of yarns or *threads* of which they are composed. Their names imply the uses for which they are intended. Ratline-stuff is a little larger than seizing-stuff of the same number of threads, and it is also laid up with less twist, by which it is rendered more pliable. The threads may be spun by hand or by machinery, but they must be tarred before being twisted and laid. The larger sizes of ratline- and seizing-stuff are made by the same machinery as the various sizes of rope, the strands being *tubed*, or drawn through tubes, into which they fit closely, previous to being twisted. The smaller sizes, however (12-thread and less), are not tubed, but the threads are extended to their full length and twisted to form the strand, and the strands are then laid. The machine for this purpose is similar to that used in the manufacture of rope, but is of more simple construction. See Rope.—*E. T. Strong, Lieutenant U.S.N.*

Smart-money (*Eng.*). The pension given for wounds.

Smart-ticket (*Eng.*). A certificate from a captain or surgeon, for a pension for wounds.

Smasher (*Eng.*). A seaman from the north of England.

Smear-dab. A kind of flat-fish; the *Pleuronectes lævis.*

Smelt. A small fish (*Osmerus eperlanus*), allied to the salmon. It is of a silvery-white color, and is highly esteemed as a delicate food. It emits a peculiar odor, whence the name; called also *spirling.*

Smerlin. A certain fish; *Cobitis aculeata* of Linnæus.

Smew. The *Mergus albellus*, or white-headed goosander.

Smith, John, was born at Willoughby, Lincolnshire, England, in January, 1579. In 1606–7 he was associated with Newport in his expedition to Virginia, and was left there to manage the little colony at Jamestown. In 1608 he surveyed the Chesapeake Bay, Chickahominy and Potomac Rivers, and gave names to several of the islands he encountered on the voyage, and also made a map of his voyage of discovery. In 1609 he left Virginia never to return. In 1614, with two ships, fitted out by some London merchants, he explored a large portion of the North American coast, to which he gave the name of New England, and of which he formed a tolerably accurate map. In 1615 he made another voyage to New England for the purpose of founding a colony, but was captured by a French man-

of-war and taken to New Rochelle. Afterward he claimed to have participated in sea-fights for the French against the Spaniards. About 1616 he received the title of Admiral of New England, and was thenceforth engaged in promoting American colonization by means of a series of publications on America, written either by or for him. He died in London on June 31, 1631.

Smith, Melancthon, Rear-Admiral U.S.N. Born in New York, May 24, 1810. Appointed from New York, as acting midshipman, March 1, 1826; from July 22, 1826, to June 15, 1830, attached to frigate "Brandywine" and sloop "Vincennes," Pacific Squadron; Naval School, 1831; frigate "Potomac," May 3 to June 28, 1831; navy-yard, New York, from June 28, 1831, to January 19, 1832.

Promoted to passed midshipman, June 1, 1832; sloop "St. Louis," West India Squadron, August 8, 1832, to December 14, 1832; navy-yard, Pensacola, December 14, 1832, to July 21, 1833; brig "Porpoise" and sloop "Vandalia," West India Squadron, from July 21, 1833, to August 15, 1834; navy-yard, New York, July 20, 1835, to November 4, 1835.

Promoted to master, 1836; sloops "Natchez" and "Vandalia," West India Squadron, from 1836 to 1838.

Commissioned as lieutenant, March 8, 1837; steamer "Poinsett," operating against the Indians in Florida, from June, 1839, to March, 1840; commanded a fort and a 20-oared barge for one month, in 1839, during the Florida war; navy-yard, New York, 1841; sloops "Fairfield" and "Preble," Mediterranean Squadron, from April 23, 1841, to September 5, 1843; receiving-ship at New York, from November, 1843, to October, 1844; store-ship "Erie," from October, 1844, to December, 1844; sloop "Vandalia" and steamer "Colonel Harney," Home Squadron, from December, 1844, to January, 1846; executive-officer of Pensacola Navy-Yard, January, 1846, to April, 1848; frigate "Constitution," Mediterranean Squadron, from September, 1848, to January, 1851; waiting orders, 1851.

Commissioned as commander, September 14, 1855; executive-officer of frigate "Potomac," while she was flag-ship to Flag-Officer Paulding, June, 1855, to October, 1855; light-house inspector, October, 1857; commanding at different times the steamers "Mississippi," "Massachusetts," and "Monongahela," Gulf Blockading Squadron, from May 1, 1861, to June 22, 1863. While commanding the "Massachusetts," engaged a fort at Ship Island, July 9, 1861, and 3 Confederate steamers and a revenue-cutter off Ship Island in 1861; engagement with rebel steamer "Florida," Mississippi sounds, October 26, 1861; cut the telegraph-wire between Shieldsboro' and Pass Christian, September 20, 1861; capture of a battery of 2 guns at Beloxi; December 31, 1861, while commanding the steamer "Mississippi," was in the attack and passage of Forts Jackson and St. Philip, and the capture and destruction of the rebel ram "Manassas," April 24, 1862. Flag-Officer Farragut, in his official report, says, "Just as the scene appeared to be closing, the ram 'Manassas' was seen coming up under a full head of steam to attack us. I directed Capt. Smith, in the 'Mississippi,' to turn and run her down. This order was instantly obeyed by the 'Mississippi,' turning and going at her at full speed. Just as we expected to see the ram annihilated, when within 50 yards of each other, she put her helm hard-a-port, dodged the 'Mississippi,' and ran ashore. The 'Mississippi' poured two broadsides into her, and sent her drifting down the river a total wreck. Thus closed our morning's fight." Chalmette batteries, below New Orleans, April 25, 1862.

Commissioned as captain, July 16, 1862.

Capt. Smith remained in the "Mississippi," taking part in all the engagements of the squadron until March 14, 1863, when, in attempting the passage of the batteries at Port Hudson, the "Mississippi" grounded in 23 feet of water, and keeled over to port. Every effort was made to get the vessel off, but without avail, and the enemy having obtained the exact range of the ship, were hulling her at almost every shot, when Capt. Smith gave orders to fire her, which was done in four different places between decks. When the flames had gained sufficient headway to render the destruction of the vessel certain, Capt. Smith gave orders to abandon her, which was done quietly and without confusion, he being the last man to leave. By his cool and courageous bearing in the trying situation in which he was placed Capt. Smith won the admiration of all, and his course was approved by both Rear-Admiral Farragut and the Department. While commanding the "Monongahela," participated in the attacks on Port Hudson, from June 1 to 20, 1863; from June 22, 1863, to July, 1863, under orders North to report for a command,—reporting July 7, 1863; from July, 1863, to February 15, 1865, at sea, commanding ironclad "Onondaga"; temporarily transferred, April 23, 1864, by telegraph, to command of squadron in North Carolina sounds, to capture rebel ram "Albemarle"; engaged that vessel and her consort, the steamer "Bombshell," in Albemarle Sound, capturing the latter vessel May, 1864; returned to "Onondaga" as divisional officer on James River, and was permanently transferred to frigate "Wabash," for operations against Fort Fisher; participated in both attacks on Fort Fisher; 1865, navy-yard, Washington, D. C.

Commissioned as commodore, July 25, 1866; chief of Bureau of Equipment and Recruiting, Navy Department, 1866–70.

Commissioned as rear-admiral, July, 1870; commandant navy-yard, New York, 1870–72. Retired March 24, 1871.

Smiting-line (*Eng.*). A line by which a yarn-stopped sail is loosed, without sending men aloft.

Smoke. A dense, sandy vapor on the coast of Africa.

Smoke-ball. A ball which, when fired, burns with a dense smoke for several minutes.

Smoke-box. A chamber connected to a steam-boiler, in which the gases of combustion collect after having performed their work, and from which they are discharged into the smoke-pipe; as, the smoke-box of a locomotive. The term is synonymous with *front connection* and *uptake* as applied to marine boilers.

Smoke-pipe. The metallic chimney or funnel of a steam-boiler furnace. The term *smoke-stack* is in common use; but the word *stack* implies a chimney of masonry. See FUNNEL.

Smoke-sail. A piece of canvas fastened to

two small yards, hoisted on the foremast to prevent the smoke from the galley from soiling the mast. *To reef the smoke-sail*, to take it in entirely.

Smoke-ship. A novel fire-ship, invented by Meesters in 1794. See FIRE-SHIPS.

Smoke-stack. See SMOKE-PIPE.

Smoking-hours. Certain hours are designated on board men-of-war when the men may smoke. These are, during meals, half an hour after the men are called in the morning, holidays, Sundays, Saturday afternoons, and after hammocks are down, until 8 P.M.

Smoking-lamp. A small lamp with a hole in it, lit during smoking hours, so as to furnish a light for pipes.

Smolt. A salmon of from 4 to 6 inches long, and a little more than a year old, that has acquired its silver scales.

Smorth. A clear spot in the surf.

Smug-boat. A Chinese opium smuggler.

Smurlin. A mollusk; the *Mya truncata*.

Snacot. A certain fish; the gar-pike; the sea-needle.

Snag-boat. A boat used on rivers with machinery for removing snags.

Snake. To pass turns of a rope, then to pass turns across, winding from one to the other. To wind small ropes spirally between two larger ones. Backstays are snaked together, to prevent them from falling, if shot away singly.

SNAKING. Turns of a rope passed in a zigzag direction, or spirally, between two other ropes.

Snape. To cut the end of a timber off beveling, so as to fay upon an inclined plane.

Snapper. The red snapper, *Serranus erythrogaster*, a fish well known in the West Indies.

Snarl. *In a snarl*, in disorder; confused; tangled.

SNARL-KNOT. A knot that cannot be undone.

Snarley-yow. A discontented grumbler.

Snatch. To place a rope in a block for a proper lead. A *snatch* is an open lead, whether in a block or cleat. In the latter case it is called a *dumb snatch*.

SNATCH-BLOCK. An iron or wooden block with an aperture into which the bight of a rope may be introduced. They are generally of wood, and an iron strap closes the aperture; or they hinge at the hook, and close by shutting the block and clasp attached. A large snatch is called a *voyal*.

SNATCH-CLEAT. A curved cleat or chock, through which a rope may be led.

Sneer (*Eng.*). *To make all sneer again* is to strain spars and sails by "cracking on," or crowding sail.

Sneezer. A stiff gale.

Snifting-valve. A valve controlled by a spring or weight, used in the earlier forms of steam-engine previous to the adoption of the air-pump, for expelling the air and uncondensed vapor from the cylinder, which also acted as a condenser, by the impulse of the piston and its attachments. The term is now frequently applied to *cylinder relief-valves* when their action is automatic.

Sniker-snee. A fight with knives.

Snipe-fish. The bellows-fish.

Snood. A small piece of hair fastening a fish-hook to the line.

Snook. The sea-pike; the *Thyrsites atun*.

Snorter, or Snotter. A small rope bent to the end of a light yard, over which fits the eye of the lift and brace. The tripping-line leads from the other end of it to the deck, and when hauled upon pulls off the lift and brace.

Snotter. A small grommet about a mast, with an eye in it, in which a *sprit* ships.

Snow. A two-masted vessel with a boom-mainsail set on a trysail mast.

Snub. To check the motion of anything.

SNUB-POST. A bollard, or post on a dock, for fastening ropes to, in order to check a ship.

SNUBBER. A check-stopper.

Snug. A piece for wedging or otherwise combining two or more other pieces together. In a safe situation; prepared for the worst.

Sny. The line or shape given to planking put upon the curving surfaces at the bow or stern of a ship. The upward curving of the planking at the bow or stern. It is sometimes called the *spiling*.

So! Well! Right as it is!

Soak and Send (*Eng.*). Word passed for wet swabs.

Soam. The dried air-bladder of herring.

Soap, Salt-water. Soap made from cocoa-nut or palm-wood oil. It solidifies with 75 per cent. of water.

Socket. A hole into which a spindle fits. *Capstan-socket*, the socket for the capstan-spindle. *Pivot-sockets*, gun-metal sockets placed in the decks to receive the pivots of gun-carriages.

Sod-bank. The refraction of banks in the water.

Soft-laes (*Eng.*). Small coves and bays worn in soft cliffs by the action of the waves.

Soft-plank. An easy berth on the deck.

Soft-tack, or Soft-tommy. Soft bread, or fresh-made wheaten bread.

Solan-goose. The gannet, *Sola bassana*.

Solano. The sirocco.

Solar. Pertaining to the sun. See DAY, ECLIPSE, TIME, YEAR.

Soldier. A derisive term for a poor sailor. *To soldier*, to make a pretense of working without expending much force; to play the *old soldier*. The antagonism long existing between the sailor and the soldier is likewise manifested by the adage, "*Tell that to the marines*," implying that they will believe anything.

SOLDIER-CRAB. The hermit-crab.

SOLDIER'S-WIND. An especially fair wind, so that a passage may readily be made.

Sole. A marine flat-fish (*Solea vulgaris*) which, with allied species, is peculiar, among vertebrate animals, in having both eyes placed on one side of the head, namely, that side which is uppermost when they are swimming. It remains at or near the bottom of the sea. It sometimes grows to the weight of 6 or 7 pounds or more.

An additional piece on the bottom of the rudder. The lining of bilge-ways and ports.

Solid Shot. A compact projectile used for battering purposes, and distinguished from hollow shot, grape, canister, shrapnel, etc.

Solstices (from Lat. *sol*, the sun, and *stare*, to stand still). The two periods of the year, about June 22 and December 22, at which the sun attains his maximum declination. When the sun, in his annual revolution in the ecliptic, has attained his greatest northern declination, his course for the moment is parallel to the equinoctial, and, as far as change of declination is con-

cerned, he appears "to stand still"; and similarly he appears "to stand still" when at his greatest southern declination. They are distinguished as the *summer solstice* and the *winter solstice*. We must bear in mind, however, that these terms are relative, for what is the summer solstice in the northern is the winter solstice in the southern hemisphere, and what is the winter solstice in the northern is the summer solstice in the southern hemisphere.

Solstitial Colure. The hour-circle which passes through the solstitial points. See COLURES.

Solstitial Points. The two points of the ecliptic at the greatest distance from the equinoctial. They are distinguished as the *summer solstitial point* and the *winter solstitial point*, and called also the *first point of Cancer* and the *first point of Capricorn*, as being the commencement respectively of these signs of the ecliptic. They are represented by the symbols of these signs, ♋ and ♑. The figure of the *Crab* (Cancer) has evident reference to the sideways and backward motion of the sun at this point of his orbit. The solstitial points, like the equinoctial points, do not preserve a constant place among the stars, but have a slow retrograde motion.

Soma. A Japanese junk.

Song. The chant used by merchant sailors in hauling. The call formerly used by the leadsman in giving the soundings obtained. See NAVAL SONGS.

Son-of-a-gun. Originally, a boy born afloat. A term of slight contempt.

Sops (*Eng.*). Detached clouds hanging about mountain tops.

Sothis. The Egyptian name for the star *α Canis Majoris*. See SIRIUS.

Sou'. A colloquial abbreviation for *south*.

Sough. The sighing or hollow sound made by the wind, especially before a gale.

Sound. A cuttle-fish. The swimming-bladder of a fish. To measure the height of the water in the pump-well. To measure the depth of water in the sea, by means of a line and weight, or by some machine devised for the purpose. See DEEP-SEA SOUNDING, LEAD. A whale *sounds* when it dives upon being struck with a harpoon.

Narrow passes which connect larger bodies of water receive many designations. Among these, *sound* is used to designate some, but far more are called *strait*. The three terms, *strait*, *channel*, and *sound*, are interchangeably used to name such passes. Besides these, in many places, the word *passage* is used. Some straits are called *belts* in the Baltic, *firths* in the Scottish isles, and *pertuis* on the French coast. The words *canal* and *canale*, in Italy and Austria, designate sounds and straits. A sound or a channel is supposed to be larger than a strait or passage, but such is not always the case.

Great numbers of these water-passes exist, straits being the more numerous, and sounds next, while channels and passages are not far behind.

The principal sounds and straits of Europe are those connecting the Baltic with the North Sea, the latter and the Irish and Mediterranean Seas with the ocean, and the various seas and gulfs of the Mediterranean basin with the ocean, or with each other. The Baltic waters find their way out through a succession of passages, called in succession Skager Rack for 150 miles, Kattegat for 120 miles, and the Sound 26 miles. The smaller passages about the Danish islands are named belts, the chief being the Great Belt, Little Belt, Langeland Belt, and Fehmern Belt. In the Baltic itself are Kalmar Sound, and several small passes.

The North Sea connects with the English Channel by the Strait of Dover. The two passages are 270 miles long, and from 45 to 18 miles wide. The Irish Sea connects with the Atlantic through St. Patrick's and the North Channel, and through St. George's Channel. These are wide sounds, and there are innumerable passages, sounds, etc., among the many islands of this sea.

The Strait of Gibraltar connects the Mediterranean with the Atlantic, and the other principal straits of this sea are Bonifaccio, Messina, Otranto, and the Dardanelles and Hellespont Channels, through which the various seas connect with the larger Mediterranean. The passages separating the Ionian isles are generally called channels, and are narrow and deep.

Asia is separated from America by Behring's Strait, connecting the Pacific and Arctic Oceans. The numerous seas that indent the Asiatic coast are connected with one another and with the ocean by passages, channels, straits, and sounds innumerable, chief of which are La Perouse Strait, Corean, Fo-Kien, Balintang, and Bashee Channels, Malacca Strait, Falk Channel, and the Straits of Ormuz and Bab-el-Mandeb. The islands of Malaysia and Melanasia are separated by similarly-named passages, the largest of which are Macassar, Sunda, Torres, and Bass Straits, and Gilolo, Molucca, and Pitt Passages.

The Mozambique Channel, on the African coast, is one of the largest sounds. It is 1000 miles long, and from 240 to 480 wide.

The many islands in the Frozen Sea, north of America, are separated by straits, sounds, and channels, named to perpetuate the memories of their discoverers or their countries' sovereigns, cities, or great men. Davis and Hudson's Straits and Melville Sound are the largest. Here we also find sounds that are really bays,—Albert, Kotzebue, and Norton Sound being such bodies of water. On the coast of the United States are many shallow sounds, and in the West Indies are large channels and passages. On the southern coast of South America are numerous straits and channels, the largest being the Strait of Magellan.—*F. S. Bassett, Lieutenant U.S.N.*

SOUND-DUES. Tolls formerly levied on all shipping passing into the Baltic Seas.

SOUNDING-LEAD. See LEAD.

SOUNDING-LINE. A lead-line.

SOUNDING-MACHINE. Several machines have been invented to facilitate sounding. *Massey's lead* measures the depth by the revolution of a fan, set in an ordinary lead, with counter-wheels attached. *Walker's harpoon sounding-machine* is on the same principle. The *self-registering lead* was invented to measure the depth by the compression of the air contained in a tube, and several modifications, Ericsson's among others, have been made, but none are in general use. *Trowbridge's electric sounding apparatus* has a line coiled in a small cylinder, with a wire inside the line. When the lead strikes the bottom, the circuit is completed, and announced on deck. It is not successful.

Sigsbee's Sounding-machine.—Slightly in ad-

vance of the reel, which is practically the same as that in the Thomson apparatus, are two pipes parallel to each other and about 6 feet in height, each containing a spiral extension spring fastened at the bottom and connecting, by means of ropes taken over pulleys at the top of the pipes, with a cross-head moving between the two pipes, the latter serving as guides. The cross-head contains a pulley, one yard in circumference, over which the wire leads in its passage from the reel to the water. The normal position of the cross-head is at the top of its guides, and it can be borne down only against the resistance of the springs. By this means a very sensitive accumulator is provided to ease the jerks on the wire while reeling in, and which also shows, by a graduated scale on the pipes, the amount of strain upon the wire at all times during the same operation, thus acting as a dynamometer. An odometer attached to the axle of the cross-head pulley gives without reduction the number of yards of wire payed out or reeled in.

In paying out no weights are used for tightening the friction-line, but the latter is connected with the cross-head in such a manner that the resistance of the springs is made available for the purpose stated. This arrangement also operates as an automatic governor on the motion of the reel when paying out wire in a sea-way. During the downward plunges of the vessel, when the strain upon the wire is suddenly eased, the operation of the governor is to increase the strain on the friction-line, slowing down the reel and preventing the wire flying from the drum. As the decreased speed of the reel or the rising of the vessel restores the tension upon the wire the friction-line is eased in turn, and the reel permitted to revolve more rapidly. At the instant when the sinker strikes bottom the governor automatically increases the resistance upon the reel. There are various accessories to facilitate operations and to insure the safety of the wire. The machine as now constructed is almost entirely of steel, and has a small steam-engine attached. The apparatus folds in such a way that the whole may be stowed in a box of small dimensions.

Sir William Thomson's Sounding-machine.— This machine is designed for the purpose of ascertaining accurately and quickly the depth of water under a ship, without stopping or even reducing her speed.

The apparatus consists of a light wheel on which is coiled about 300 fathoms of piano-forte steel wire. The stand to which the supports of the wheel are attached is fixed to the taffrail, at the stern of the vessel, so that the sinker can be left hanging ready for a cast. A cord wound round a groove in the circumference of the drum, is so arranged as to form a self-acting brake, which when the sinker is hanging offers enough of resistance to prevent it from running down, but when it is being hauled in offers very little resistance to the turning of the wheel. When the order is given to take a sounding the brake is released by the hand, so as to leave a force of about 7 pounds pulling on the rope, by which a resistance of about 5 pounds is opposed to the wire while it is running out. Thus, when the sinker reaches the bottom the wheel suddenly stops. The brake is then applied to prevent it from running on again.

The sinker is a long iron weight of 22 pounds, with a hollow at the bottom to receive the usual arming of tallow, etc., to bring up a specimen of the bottom. It is attached to the end of the wire by means of a rope 6 or 8 feet long.

A brass tube a little more than 2 feet long is lashed to the rope connecting the sinker with the wire. A glass tube, 2 feet long, coated inside with chromate of silver, and closed at one end and open at the other, is placed with its open end down, in the brass tube. As the sinker descends the increased pressure drives the sea-water up the glass tube, which, combining with the chromate of silver, makes a white mark. The height of the white mark registers the height to which the liquor has been forced up the tube. A scale, graduated to fathoms, shows at once the depth to which the glass tube has been. This method of taking soundings depends on the increased pressure as the tube descends, but is independent of the amount of line out, so that the vessel does not require to be stopped in order to take a sounding.

The advantages of wire over rope of the same strength, are the smallness of area and smoothness of surface, on account of which it experiences very little resistance when pulled rapidly through water. This allows the sinker to descend very quickly, and to be hauled on board again with great ease, so that two men working the machine can take soundings in 100 fathoms every few minutes, from a ship running at any speed, up to 16 or 17 knots.

When the machine is not required for immediate use, the drum must be kept in the iron tank covered with lime-water.

Sounding-pole. A pole used in sounding by small craft in rivers. They are represented in Egyptian wall-paintings of 1800 B.C.

Sounding-rod. A rod, marked in feet and inches, and suspended by a line, used to sound the pump.

Soundings. The depth of water ascertained by the lead. *On soundings*, within the 80-fathom line. Soundings are expressed in fathoms on charts, except in French charts, where metres are used. See Fathom, Deep-sea Sounding.

Souse. To immerse suddenly in a fluid.

Soused-gurnet (*Eng.*). A pickled fish.

South. The region, and the point of the compass, directly opposite to the north. All Teutonic and Latin races use the same word, except Italians, who call it *Ostro*.

Southampton. A seaport town of England, on a peninsula at the mouth of the Itchen, near the head of Southampton Water. Lat. 50° 44′ N.; lon. 1° 24′ 2″ W. The manufactures, except ship-building, which is carried on to a large extent, are chiefly confined to brewing, coaches, castings, silk goods, carpets, and the refining of sugar. The town is a very important steam-packet station, and is much visited by ocean-steamers. It has very fine docks, and is an emigrant station. Pop. 54,000.

South-easter. A southeasterly gale is generally wet on the American coast, but dry and hot in the Mediterranean.

Southing. The distance in nautical miles which a ship makes to the southward.

South-wester. A southwesterly gale, accompanied by rain on the American and English coasts. A storm-hat of painted canvas, oiled

cloth, silk, or rubber, with broad brim or flaps to protect the neck.

Spain, Navy of. The discovery of the New World by Christopher Columbus naturally led the government of Spain to extend the desire for exploration and possession in the southern parts of the western hemisphere. This necessitated the construction of more ships for purposes of traffic and travel; and in anticipation of the hostility of other nations possessing like maritime resources, and inspired by the same designs, a navy became ultimately necessary. The 16th century, however, had seen eight decades before any very decided steps were taken to give employment to the armament which Philip II. had devoted so much time and treasure to raise. In 1587, after several contests with the Dutch in the great War of Religion, the king of Spain had at command a force of 130 magnificent ships of war, well manned and equipped, and with these he determined to make a descent upon England, with the avowed purpose of taking possession of the country and punishing and converting the heretics. The "Invincible Armada" was the pompous title given to the hostile expedition. It left the Spanish coast, under the command of Admiral Medina Sidonia, in the summer of 1588, a year later than was intended, but Admiral Drake had, in the interval, crossed to the Spanish coast and destroyed 100 vessels laden with stores of war, besides intercepting and capturing a large treasure-ship. After a few skirmishes and isolated combats on the passage, the Armada was confronted by an English fleet on the 8th of August. The great height and tonnage of the Spanish ships making them rather unmanageable when evolutions were attempted, conspired to place them at a disadvantage in the great battle that ensued. After a combat, which lasted an entire day, as many of the Spanish men-of-war as had not been crippled or captured sailed away in a northerly direction to avoid the Dutch and English cruisers in the Channel. In the North Sea they experienced a heavy storm, which shattered so great a number that, on the arrival of the remnant of the Armada in the harbors of Spain, scarcely one that had escaped was entirely uninjured. But the enormous wealth of the nation, arising out of its possessions in the Indies, enabled it rapidly to recover from its disasters, and during the two centuries that ensued Spain held her own, now against England and France, now associated with the latter power. Ultimately, however, the naval forces of her antagonists prevailed, and as the loss of her foreign possessions, either through wars or rebellions, reduced her resources and limited the field for the employment of her ships, she gradually declined as a naval power, and her navy is now represented by 11 armor-clad vessels, 9 wooden screw-frigates, 10 screw-corvettes, 10 paddle-wheel corvettes, 2 avisos, 75 gunboats, 17 other steamers, and 4 sailing-vessels, a total of 138. None of her fighting-ships possess either the armor, speed, or armament to compare with lately constructed armor-clads. The "Numancia" and the "Vitoria" are the most powerful of the armored ships. They are rated as line-of-battle ships, have broadside batteries and ram bow, and are built of iron. Both of the above vessels are of the same general dimensions; the principal difference is in the armor and armament. The "Numancia's" plates are 5 inches thick at the water-line, and she carries six 18-ton guns, three 9-ton, and sixteen 7-ton, all Armstrong rifles; the "Vitoria's" armor is 5½ inches thick at the water-line, and her armament consists of four 12-ton, three 9-ton, and twelve 7-ton Armstrong guns. The minister of marine is invariably chosen from the grades of vice- or rear-admiral, having two sub-secretaries (rear-admirals). The corps and grade divisions of the active *personnel* correspond with those of other nations, the grades of the executive corps being as follows:

Almirante, vice-almirante, gefe de escuadra, capitan de navio, capitan de fregata, teniente de navio (1a cl., 2a cl.), alfarece de navio, guardia marina.

The grades of the medical corps are medical inspector, medical sub-inspector, surgeon-major, first surgeon, second surgeon.

The grades of the commissary corps are superintendent, purveyor (1st class, 2d class), commissary (1st class, 2d class), first assistant commissary, second assistant commissary, third assistant commissary, supernumeraries.

Chaplains have their grade and rank also. Sub-vicar-general, first chaplain, second chaplain, sacristan (lay official), chorister (lay official).

The technical corps includes the ship and engine constructors, and have the grades of general officer, brigadier, ship-of-the-line captain, frigate captain, lieutenant, ensign.

The corps of machinists who work the engines are graded as first, second, third, fourth, and assistant machinists. The total active *personnel* of the fleet is 1792 officers (exclusive of chaplains, midshipmen, and the technical corps). There is also a marine artillery corps, the officers of which are 1 general officer, 3 colonels, 7 lieutenant-colonels, 16 captains, 20 lieutenants, and the marine infantry corps, which is divided into 2 half brigades of 2 battalions each, and 2 companies of native infantry in the Philippines. The strength of this corps is 170 officers and 6256 men, making a grand total of 1962 officers and 20,256 men in the Spanish navy. The Naval Academy at Ferrol furnishes all the officers of the executive corps of the service. There are also special schools under naval control for the education of pilots of the merchant service, one for machinists, and an academy for the artillery and technical corps. The Hydrographic Bureau and Naval Museum are located at Madrid, and the Naval Observatory at San Fernando. The annual expenditure for the navy is a little over $5,000,000.

Spake-net. A net for catching crabs.

Spalding-knife. A Newfoundland knife for splitting fish.

Spaldings (*Eng.*). Whitings and other small fish.

Spales, or Spaling. Cross-bands placed so as to keep the frames of a wooden or iron ship in place until beams, planking, or plating are put on.

Span. A rope having both ends made fast, so that a purchase may be hooked in the bight. A rope made fast to a stay or shroud in the centre, so that both ends may be used. To connect by ropes. *To span in the rigging*, to draw the topmast rigging together by tackles; to seize on the

catharpin-legs. Span of the rigging, the distance over the mast-head, from the dead-eye on one side to that on the other. *Spanning a harpoon*, fixing the harpoon-line to it. The staff ships in an iron socket, but is not fast, and the line runs through a becket on the staff, and through the socket, making fast to the head of the harpoon. The staff disconnects on striking, but is retained by the line.

SPAN-BLOCKS. Blocks seized into each bight of a strap that leads across a cap or mast-head, so as to hang down on either side.

SPAN-LASHING. The lashing of a span, or a lashing that spans the distance between two ropes separated by a slight interval.

SPAN-SHACKLE (*Eng.*). A large bolt through the forecastle deck, with a triangular shackle in the head to receive the heel of the old-fashioned fish-davit. Bolts driven in the deck, by which the spars and boom-boats are lashed in place.

Spanish-burn (*Eng.*). Hiding defects in timber by hacking it with an ax.

Spanish-burton. A kind of purchase. A *single Spanish-burton* has two single blocks, the upper, the standing block, with a tail or hook to it, the lower having the standing end of the fall made fast to its strap. The weight is applied to the bight of the fall between these blocks by means of a hook. *Double Spanish-burtons* have three blocks, all single or one double, two blocks being movable and one fixed, and the weight is applied to the lower of these. The fall is in two parts,—one secured to the strap of the leading block, and the other to the lower block, or to the upper one. The increase of power is from 3 to 5 times that applied.

Spanish-fox. A single yarn twisted up left-handed, or contrary to its lay.

Spanish Mackerel. The tunny-fish.

Spanish Reef. The yards are lowered on the cap, but the reef-tackles are not hauled out, as in a *monkey-reef*. A knot tied in the head of a jib.

Spanish Windlass. A wooden roller, with a rope wound about it, into which a marling-spike is thrust to serve as a lever. A purchase formed by several turns of a rope around two parts of a piece of rigging, both ends being hauled upon.

Spanker. The aftermost sail in a ship; a fore-and-aft sail, setting abaft the mizzen-mast, having a gaff, and generally a boom. Formerly called the *driver*. Until the middle of the last century a lateen-sail was used instead of the spanker. For the rigging of a spanker, see under the proper heads.

Spanker-eel (*Eng.*). The lamprey.

Spanking. Large; fine; strong. *A spanking breeze*, a fine, fresh breeze. *A spanking frigate*, a large, fine frigate. *To go a spanking*, to sail with a fine breeze aft, or quartering.

Spanner. A wrench fitted to gripe and turn a cylindrical piece; as, a *hose-spanner* or wrench with which hose-couplings are manipulated.

Spar. Any round piece of timber used for a mast, yard, boom, etc. *A shifting spar* is a light spar, with a hook or a grommet attached, used to shift a light gun from one carriage to another. *A torpedo-spar* is one used to thrust a torpedo from a ship's side or bow. *Spare spars*, see SPARE.

SPAR-DECK. See DECK.

SPAR-MAKER. A carpenter whose especial trade is the fabrication of ships' masts, yards, etc.

SPAR-PILE. The collection of spare spars on the deck. The locality is called the *booms*.

SPAR-SHED. A shed or shop in a navy-yard where spars are fashioned.

SPAR-TORPEDO. See TORPEDO.

Spare. A general term for all reserve stores put on board ship, as spare sails, spare spars, etc.

SPARE ARTICLES. Duplicate sets of small castings, etc., placed under the care of the yeoman. Also, extra sets of gear for the service of the guns issued to each division, such as sponges, breechings, trucks, etc.

SPARE ANCHOR. An additional anchor, the size of the bower, formerly furnished to ships. It is now replaced by one of the sheet-anchors.

SPARE SPARS. Certain spars furnished in duplicate. These are fore- and main-topmasts, fore-yard, fore- and main-topsail yard, topgallant and royal yards, and studding-sail booms. Spare spars are not furnished so liberally to steamers, not being so essential to their safety. They are placed in the *spar-pile*, or on cranes in the channels on either side.

Sparling. The *smelt*.

Sparoid. Belonging to a family of spinous-finned fishes, which include the gilt-head, sea-bream, and porgee.

Spat. The spawn of the oyster.

Speak. *To speak a vessel*, to pass within hail and communicate with a ship by voice.

Speaking-trumpet. See TRUMPET.

Specific Gravity. See GRAVITY.

Speck. The blubber of whales.

SPECK-BLOCK. The block through which the *speck-falls* are rove.

SPECK-FALLS. Ropes rove through the speck-blocks, at the mast-head of a whaler, and connected to the *blubber-guy*; used for hoisting the blubber strips.

SPECKTIONEER. The chief harpooner, who also superintends cutting and stripping the blubber.

Speed of Ships. Ships under sail make from 5 to 15 miles an hour, with good breezes. Their speed varies much with the direction of the wind, its force, and the state of the sea. Ships sail slower close-hauled than when free, and better with a side wind than when it is aft. The average rate of sailing is about 120 miles per day. Clipper-ships have far surpassed this, and the "Sovereign of the Seas" averaged 19 miles an hour in a trip to San Francisco. Yachts have made nearly as much, and greater speed has been attained by sailing-catamarans. The speed of steam-vessels is gradually increasing. Two hundred miles a day is thought to be a fair average, but steamers make as much as 20 or 22 miles an hour. Some boats have made 25 miles, and even more, in smooth water. An average speed of 10 knots is thought no longer to suffice, and men-of-war should be able to steam 15 miles in a moderate sea.

Speed-indicator. A log, fixed on the taffrail or at the stem, so that the speed of the vessel is at any time ascertained by looking at it. See LOG.

Spell. A short period employed in work. A relief or temporary respite from labor. A spell at the wheel is called a *trick*. *Spell ho!* a call for a relief. *To spell*, to relieve at any work for a short time.

Spencer. A trapezoidal sail setting on a mast

and gaff, without a boom, invented by Knight Spencer, in England, in 1802. *Fore-spencer*, the fore-trysail. *Main-spencer*, the main-trysail. For the gear of a spencer, see under proper heads.

SPENCER-MAST. A trysail-mast, stepped abaft the principal mast.

Spent. Having lost power; as, a *spent shot*, a *spent mast*, etc.

Sperm-whale, or Spermaceti-whale. A large, square-nosed whale, the *Physeter macrocephalus*, or cachalot, of the Delphinoid or toothed order of Cetaceans. It is found in tropical and temperate seas, and its oil is very valuable. It attains a length of from 60 to 80 feet, the head, containing the oil, being a third of this length. See CACHALOT.

Speronare. An Italian boat, having two masts with lateen-sails, the foremost raking forward.

Spew Oakum. The seams are said to *spew oakum* when, from heat or working, the oakum starts from between the plank.

Sphera Nautica. A navigating instrument used in 1570.

Spherical-case. See SHRAPNEL.

Spica (*Lat.* an ear of corn). The name of the bright star *a Virginis*, so called after the device of the ancient Greeks, who placed an ear of corn in the hand of the Virgin, typical of the harvest, which with them coincided with the sun's approach to this conspicuous star. See VIRGO.

Spider. An iron outrigger, to keep a block clear of the ship's side, of the funnel, etc.

Spider-band, or Spider-hoop. An iron band around the lower mast, to which the futtock-shrouds are attached by hooks inserted in eye-bolts in the band. A band around a mast, with sockets attached, into which belaying-pins are thrust.

Spider-crab. The sea-spider.

Spike. To drive spikes in plank or timbers. To close the vent of a gun by driving a steel spike into it. A cut or wrought nail, larger than 10d, used in boat- and ship-building. *Boat-spikes* are from 3 to 10 inches long, and there are from 2 to 17 of them to the pound. *Ship-spikes* are stouter, from 4 to 10 inches long, and there are from 1 to 8 in a pound. A round steel file or rod, used to close the vent of a gun. *Spring-spikes* have a spring at the lower end, to retain them in place. A handspike.

Spike-plank. A bridge across the deck of Arctic vessels.

Spike-tackle. The tackle used by whalers to hold the whale alongside while stripping it.

Spike-tub. A tub receiving the fat, blubber, etc., of whales, until it is rendered.

Spile. A pin driven in a nail-hole. A pile. A spigot. A wooden peg in a small hole in a cask containing a liquid.

SPILE-HOLE. An air-hole in a cask. A hole for a spigot.

Spiling. The edge curve of plank or timber. Taking the shape from a curved surface, as a ship's side, by the use of a straight batten and a rule, and applying the same to a plank which is to be bent to the shape taken off.

Spill. To take the wind out of a sail by bracing the yard, by hauling up some of the gear, or by luffing the ship.

SPILLING-LINES. Ropes sometimes temporarily fitted to the courses, extending abaft the sail to the leeches, for the purpose of spilling the wind out of the sails.

Spindle. The upper main piece of a made mast. The shaft on which the capstan revolves. The stem or axis of a vane.

Spindle-valve. A disk-shaped valve which is moved and guided to and from its seat by a *spindle* or *stem*; as, in *stop-valves*, *poppet-valves*, etc.

Spingard. An old cannon.

Spire-vapor. Spiral streams of vapor rising from the surface of the ocean, seen in Arctic regions.

Spirit-ration. The ration of grog, formerly served out to the crews of our ships, and still given in some navies. It was abolished in the U. S. navy in 1862, and five cents a day is paid each man as a commutation.

Spirit-room. The room in the hold where spirits were formerly kept, under sentry's guard. It was abaft the main hold, and forward of the after-peak, and, where yet existing, is used for paymaster's stores.

Spirket. A space forward and aft, between the floor-timbers.

Spirketing. That part of the inside planking in vessels of war which is worked between the top of the water-ways and the lower port-sills. Where there are no water-ways, it is the thick strake wrought on the top side of the beams.

Spit. A narrow tongue of land or shoal. A light rain-squall. A narrow tongue of land or a shoal making out into the sea.

Spit-fire Jib. A small storm-jib used in cutters.

Spithead Nightingales (*Eng.*). Boatswains and boatswains' mates, piping their calls.

Spit-kid. A small wooden cask, set about the decks, for spit-boxes. Spitting upon decks is an unpardonable offense, and men are sometimes punished by serving as perambulating stands for spit-kids.

Spla-boards (*Eng.*). Plank fixed at an angle, to reflect light into magazines.

Splice. To unite two ropes, or to join a rope to a chain, by interweaving them. The union of two ropes, or of a rope and chain. Two ropes joined to reeve through a block are united by a *long splice*, in which the strands of each rope are replaced by those of the opposite rope, and the ends are neatly tucked under other strands. A *short splice* is made where a large diameter is not objectionable. The ends of the strands are tucked under those of the opposite rope two or three times. An *eye-splice* is one in which an eye is formed in a rope, the end being spliced into its own part. A *cut-splice* is an oval formed by splicing the ends of two ropes into the opposite rope, at 6 or 8 inches from the end. A *horseshoe-splice* is made by splicing a short piece of rope between the parts of a bight formed in a rope. A *sailmaker's splice* is one joining two ropes of different sizes, so that the splice is tapered. A *mariner's splice* is simply a long splice in cable-laid rope. A *drawing splice* is one made without tucking the ends, so that it may be drawn out. Ropes are spliced to chain, and wire ropes are spliced together by peculiar methods, and rope is spliced around thimbles and bull's-eyes.

SPLICED EYE. An eye spliced in the end of a rope. A thimble or bull's-eye is generally inserted in it.

SPLICING-FID. A tapered wooden fid, used to

open the strands of a rope. Marline-spikes are oftener used for splicing.

SPLICING-SHACKLE. A large shackle in the end of a chain, with a thimble for splicing a rope to it.

SPLICING THE MAIN BRACE. An expression denoting the act of drinking spirits. It is equivalent to "topping up the boom," and "sweating up the halliards." The Germans say "*Besahnshot an!*" "Haul aft the spanker-sheet!"

Splinter. A fragment of wood or iron broken off by the passage of a shot through a ship.

SPLINTER-NETTING. A netting formed of light rope, to prevent accidents from splinters, falling spars, etc.

Splitter. The fisherman who splits fish open after they have been *headed*.

Splitting-out. Splitting away the wedges from under a vessel's keel before launching.

Splitting the Books (*Eng.*). Opening a new set of books after paying off, in which men are continued with their old numbers.

Spoke. One of the projecting handles of the steering-wheel. "*To put a spoke into a man's wheel*" is to say a good word for him.

Sponge. A fibrous and porous substance from the sea-depths, the framework of a marine animal. An instrument for cleansing the bore of a gun. The ordinary sponge consists of the handle or staff, and a wooden head covered with alum-dressed sheepskin, and having a small spiral in the end, to bring out pieces of cloth. A *rope-sponge* has no handle, but merely a piece of rope. A *bristle-sponge*, used in rifle-guns, has, instead of sheepskin, stiff bristles, disposed in spiral strips, or straight sections, on the sponge-head. A *sectional sponge* is one whose handle is in sections, for easier manipulation in a turret. A *sponge-and-rammer* is furnished to boat-howitzers, having one of these instruments on each end of the staff. A *valve-sponge* has in the end a valve opening by pressure, allowing water to escape, and thus washing the bore. It is used in very heavy guns. *To sponge*, to clean the bore with a sponge. In some modern ships, this is done from the deck below, by depressing the gun, machinery working the sponge.

SPONGE-CAP. A canvas bag, fitted over the head of a sponge when not in use.

SPONGE-COVER. The sheepskin nailed over the head of a sponge.

SPONGE-FISHING. Sponges are procured in Grecian, Syrian, and Italian waters, and coarser varieties in the West Indian seas. They are procured by diving after them, by spearing them with a long spear from a boat, and by dredging after them. Sponges abound in the Mediterranean.

SPONGE-HANDLE, or SPONGE-STAFF. The wooden staff serving to thrust the sponge to the bottom of the bore. It is often in sections, screwed together.

SPONGE-HEAD. The wooden head attached to the sponge-staff.

Sponson. The space forward and abaft the paddle-boxes of river-steamers to increase their stability. Sponsons are made sometimes open and sometimes closed, depending upon the roughness of the water into which the vessel is to run.

SPONSON-BEAM. A projecting beam in river-steamers uniting the paddle-box with the ship's side.

SPONSON-RIM. The wale upon which the paddle-beam rests at the ship's side.

Spoon, or Spoom. To scud under bare poles.

Spoon-drift. The fine mist blown from the top of the waves, and filling the air with mist. Driving snow at sea.

SPOUT-FISH. Any marine animal that spouts, as whales, etc.

Spotts, James H., Commodore U.S.N. Appointed midshipman, August 2, 1837; made a cruise around the world in the "John Adams," 1837–40; engaged in two battles on the island of Sumatra, in 1839; in the "Delaware" and "Potomac," on the Brazil Station, 1841–42.

Promoted to passed midshipman, June 29, 1843; cruised in the "St. Lawrence," in the West Indies, in 1843, and in the "Falmouth" and "Southampton," on the coasts of Mexico and Africa, in 1844–45.

Promoted to master, April 8, 1851, and commissioned as lieutenant in November of the same year. He was on the Pacific coast, in the "Lexington," in 1846–49, and again, in the "Portsmouth," in 1851–55. During the Mexican war he was on blockade duty on the west coast of Mexico, and participated in the capture of Mazatlan, San Blas, Lapaz, etc.; in the "Michigan," 1856–58; "Cyane" and "Saranac," Pacific coast, 1858–60; "Santee," Gulf Squadron, 1861; commanded "Wanderer," Gulf Squadron, 1861–62, and the "Magnolia," in the latter part of 1862.

Commissioned as commander, July 16, 1862, and commanded the "South Carolina" in 1863; commanded the "Pawtuxet" in 1864–65; executive-officer of the Mare Island Navy-Yard, 1865–67.

Commissioned as captain, July 25, 1866; commanded the "Saranac," on the Pacific coast, in 1870–71, and the "Pensacola" in 1871–72; light-house inspector, Pacific coast, 1872–74.

Commissioned as commodore, September 25, 1873; inspector of government vessels on the Pacific coast, 1877–80. During the war of the Rebellion served in the Gulf, North and South Atlantic Squadrons on blockade duty; was in both engagements at Fort Fisher, and all the batteries on Cape Fear River up to Wilmington, and several minor engagements whilst on blockade duty during the war; was up the James River when Richmond was captured.

Spout. Whales are obliged to rise to the surface and spout at intervals varying from 10 to 15 minutes. See BLOW, WATER-SPOUT.

Sprat. A small fish (the *Clupea sprattus*), allied to the herring.

SPRAT-WEATHER. Dark days in November and December, favorable for fishing for sprats.

Spray. Water flying in small drops or particles, as from the top of a breaking wave.

SPRAY-BOARD. A strip on the gunwale of a boat to keep the water and spray from coming in.

Spread-eagle. To make a spread-eagle of a person is to lash him in the rigging with hands and feet outspread. If the topmen can get a passenger or new-comer aloft, he is thus made to pay a forfeit.

Sprig, or Sprig-bolt. A small eye-bolt with a ragged point.

Spring. A crack in a spar, rendering it de-

fective. A hawser, run out from any part of the ship to a point on shore, a buoy, etc., to turn or *spring* the vessel. A hawser, leading from the stern outside the ship, to the cable by which the ship is anchored, so as to spring her in action, or for any other purpose. To split or strain a spar. To turn a ship by means of a spring. *To spring a butt*, to start the end of a plank from its fastenings. *To spring a leak*, to begin to leak. *To spring the luff*, to luff up into the wind, so as to shake the sails slightly, and then to fill away again. *Spring of a beam*, the curve upward of a beam from a level or horizontal line,—generally from 4 to 6 inches in 40 feet.

Spring-balance Valve. A valve which is held to its seat and adjusted to a given pressure by a spring-balance; as, the safety-valves of locomotive-engines, etc.

Spring-beam. A fore-and-aft beam connecting the paddle-beams, at their outer ends.

Spring-block. A block, connected to a ring-bolt by a spring, used on tacks and sheets, for greater elasticity. Invented by Hopkinson.

Spring-forelock. A *forelock*, formed of a piece of steel bent double, so as to spring open, and keep its place.

Spring-rowlock. A rowlock, fastened in place by a spring.

Spring-searcher. A steel pronged tool to search for defects in the bore of a gun.

Spring-spike. A spike for a gun, with a spring at the lower end to prevent its withdrawal.

Spring-stay. A duplicate stay, placed apart from the main one, to serve as a substitute for it in case of injury by shot, etc.

Spring-tides (Sax. *springan*, to grow, bulge). The greatest tides, taking place after the syzygy of the sun and moon. See TIDES.

Sprit. A small spar crossing a sail diagonally from the tack to the peak, and resting in a becket at the mast, called a *snotter*. The supporting spar, or belly-spar of a pair of sheers.

SPRITSAIL. A sail formerly suspended under the bowsprit, from the *spritsail-yard*. A boat's sail, extended by a *sprit*, quadrilateral in shape.

SPRITSAIL-GAFFS. A name for the *whiskers*.

SPRITSAIL-SHEET KNOT. A knot formerly used on the spritsail-sheet, made by walling and crowning the six strands together, forming an eye or short bight, to which the sheet was bent.

SPRITSAIL-TOPGALLANT-SAIL. A sail formerly set on the flying jib-boom in the same manner as the spritsail-topsail on the jib-boom.

SPRITSAIL-TOPSAIL. A sail above the spritsail, bent to a yard hanging under the jib-boom.

SPRITSAIL-YARD. A yard formerly suspended under the bowsprit near the cap, to which the spritsail was bent. It had lifts reaching to the *cap*, and braces coming in on the forecastle, and was trussed to the bowsprit. This yard is replaced by the *whiskers* in modern vessels.

SPRITSAIL-YARDING. Thrusting a stick through the gills of sharks, etc., and turning them loose thus.

Spruce-head. See SINKING-HEAD.

Spud. A potato.

Spun (*Eng.*). Bilged, or turned back; rejected in an examination.

Spun-yarn. Small-stuff, formed by twisting together two or three old rope-yarns by a winch. See SMALL-STUFF.

49

Spur. A projecting spar. A spur-beam. A spur-shore. A projection on the bows of a ram.

SPUR-BEAM. A curved timber serving as a half-beam to support a deck, abreast of the hatchways.

SPUR-SHORES. Long timbers resting on the launching-ways, with their upper ends bolted to the ship's side.

SPUR-TUBE. See PRIMER.

Spurket. See SPIRKET.

Spurling-line. A line wound over the prolongation of the axis of the steering-wheel, and connected to the tell-tale, by means of which the needle followed the motions of the wheel. A line formerly lashed to standing-rigging, with several branches holding thimbles or fair-leaders for running-gear.

Spurn-water. The water-ways. A channel left above the ends of the deck-plank, to prevent the water from going farther.

Spy-boat. A picket-boat, or look-out boat.

Spy-glass. A small telescope for ship or field use.

Squadron. A detachment of vessels or boats employed on any particular service. The divisions of a fleet, as van, centre, and rear. Any assemblage of vessels smaller than a fleet. The fleets of the U. S. navy in various parts of the globe are sometimes called squadrons, as the European Squadron, etc. See NAVAL TACTICS.

SQUADRON, FLYING. A squadron of observation or practice, that cruises rapidly about from place to place.

Squall. A sudden and violent gust of wind, of greater or less duration. These are frequent in some localities and at some seasons, and are particularly dangerous near high land. They are generally preceded, accompanied, or followed by clouds, which, together with the indications of the barometer, serve as a warning of their approach. *White-caps* on the surface of the sea also aid the mariner in foreseeing them. As the clouds are heavy and thick, or light and thin, so, generally, will be the character of these squalls; and the character of the cloud, whether rapidly rising and flying about, or quiescent and slowly changing, also foretells more or less wind. Rain, or snow, attends many of these squalls. *A black squall* is dark and threatening, and generally attended with rain. *A heavy squall* is one attended with much wind. *A white squall* is a furious blow, generally met with on the African coast, unannounced by signs other than the white-caps, and by a rushing sound, attended by a thin, whitish haze. Rain generally accompanies it. As regards the management of a vessel in a squall, the practice of seamen differs, some luffing her up and shaking the sails until the squall has passed, or sail has been reduced, and some putting the helm up and running before the wind; which to do would depend somewhat upon the ship, the circumstances, crew, etc., but generally speaking it is more seamanlike, more general usage, and more rational to luff with a wind forward of the beam, and to bear up with a wind abaft the beam. Sail should be reduced in heavy squalls, before it comes if possible, and too great attention to the warnings cannot be paid.

SQUALLY WEATHER. Weather in which squalls are frequent.

Square. The position of the yards when horizontal and at right angles to the keel. A gen-

eral term, signifying level, flush, or in a line with any object. That part of an anchor-shank just at the stock, extending to its upper end. A very long yard, giving great breadth to the sails. To place the frames across the keel at right angles. To place the yards at right angles to the keel and horizontal. *To square the dead-eyes*, to get them in the same horizontal line. *To square the ratlines*, to get them horizontal and parallel to each other.

SQUARE-BODY. The square body comprises all those frames that are square to the centre line of the ship.

SQUARE-BUILT. With the square frames much of the same length, and with short bow and stern.

SQUARE-BUTTED. A yard-arm of a large diameter and square at the end, so as to cut a sheave-hole without detriment to the yard, is *square-butted.*

SQUARE-FORESAIL. A course, or foresail bent to the fore-yard. The monkey-foresail, or square-sail set on the yard of a sloop or schooner.

SQUARE-FRAMES. Frames square with the keel, or at right angles to it.

SQUARE IN THE HEAD, or SQUARE-BOWED. Bluff and broad in the fore-body.

SQUARE-KNOT. See REEF-KNOT.

SQUARE-MAINSAIL. The sail bent to the main-yard.

SQUARE-MARKS. Marks placed on the lifts and braces, which, when brought to a certain point, indicate that the yards are square.

SQUARE-RIBBONS. Horizontal lines in a ship's plans.

SQUARE-RIGGED. Rigged with yards and square-sails principally, although other sails are used. Having especially long yards. Dressed out in full dress.

SQUARE-SAIL. A four-cornered sail bent to a yard. The foresail of a schooner set on a yard. A cutter's or sloop's sail, boomed out.

SQUARE-SAIL BOOM. A boom, hooked to an eye-bolt in the foremast of a schooner or sloop, used to boom out the square-sail.

SQUARE-STERNED. Having a stern formed by a wing transom nearly straight, so as to give little curve to it.

SQUARE TIMBER. A timber perpendicular to the keel. A timber worked with square edges and no beveling.

SQUARE-TOPSAIL. The topsail of a sloop or schooner, set on a yard.

SQUARE-TOPSAIL YARD. The light yard on the topmast of a schooner or sloop to which a topsail is bent.

SQUARE-TUCK. A stern like a yawl-boat, which is built without counter-timbers, the transom continuing up to the top-height.

SQUARE YARDS. To get the yards horizontal and at right angles to the keel. Figuratively, to settle accounts. In squaring yards, the boatswain and his mates attend, the former going ahead in a boat, and signaling with flags, while his chief mate is on the head-spars, and interprets the signal to the other mates. *Square-yard-men* in the tops attend the lifts, and the remainder, on deck, the braces.

SQUARING-OFF. The trimming off of the projecting edges of the strakes after the vessel is planked.

Squatter. The fluttering of sea-birds on the water.

Squeegee. See SQUILGEE.

Squeteague. A fish (*Labrus squeteague* of Mitchell), found in Long Island Sound; called also *weak-fish.*

Squid. A variety of the cuttle-fish, the *Loligo.*

SQUID-LINE. A fishing-line, baited with squid.

Squilgee. Formerly, a small swab. An instrument for cleaning the water from the decks, composed of a wooden head, having a strip of rubber in a groove in its under part, and a staff attached to it. A lazy, mean fellow. A line with toggles in the end, used in setting a studding-sail. A long line bent to the snorter, in sending down light yards,—generally called a *tripping-line.*

Squirm. The twist in a rope.

Stabber. A pricker; an awl used to pierce holes in canvas.

Stable. See STABILITY.

Stability. That quality in a vessel by which, when she is disturbed by wind or wave, she tends to regain her position of equilibrium. The *moment of stability* is the moment of the couple formed by the weight of the ship and the righting forces.

Stack. A precipitous rock rising out of the sea. A pile of guns, made systematically. The *smoke-stack* (which see).

Stacken-cloud (*Eng.*). Cumulus clouds.

Stade. A station for ships. A landing-place.

Staff. A light pole on which a flag is to be hoisted. *Ensign-staff*, a staff shipped astern for the ensign. *Jack-staff*, a pole stepped on the bowsprit for the jack. A class of nautical instruments of observation. A measuring and spacing rule used in ship-building. *Cutting-down staff*, that on which is marked the heights of the *cutting-down line* from the keel. *A half-breadth staff* has marked on it the half-breadth of each beam. *A height-staff* has on it the height of each frame from the keel to the beams. *A room-and-space staff* has on it the distance between frames. The officers composing the suite of an admiral or commodore, consisting of the senior or fleet-captain, the fleet-paymaster, fleet-surgeon, fleet-engineer, fleet marine officer, secretary, flag-lieutenants, masters, ensigns, and midshipmen, and when separate from any of these, the fleet signal-officer.

Staff-captain (*Eng.*). A captain of the navigating branch of officers in the English navy.

Staff-commander. The second grade of navigating officers in the English navy.

Staff-officer. An officer attached to the personal staff of the commander-in-chief. An officer of the navy not exercising military command. Staff-officers in the U. S. navy are divided into corps, as follows: medical, pay, engineer, constructors, chaplains, civil engineers, secretaries, and professors of mathematics. The medical corps includes the surgeon-general, medical directors, medical inspectors, surgeons, passed assistant surgeons, and assistant surgeons. The pay corps includes the paymaster-general, pay-directors, pay-inspectors, paymasters, passed assistant paymasters, and assistant paymasters. The engineer corps includes the engineer-in-chief, chief engineers, passed assistant engineers, assistant engineers, and cadet engineers.

Staff-surgeon. A title used in the English navy for the senior surgeons. The next rank of medical officers above surgeon.

Stag. A rock rising from the sea.

Stage. A plank platform, or single plank used to support men while working. *Floating stage.* (See FLOATING.) *Hanging stage*, a stage suspended over the ship's side. *Cable-stage*, a platform formerly placed in the hold for cables, hawsers, etc.

Stagger. A ship is said to stagger when she has as much canvas as she will bear, and when she moves heavily in rolling.

Stain. Black staining may be done with logwood, ¼ pound; green copperas, 6 ounces; nutgalls, 8 ounces; vinegar, ½ gallon, applied warm. Or, ½ pound logwood boiled in water, with 1 ounce pearlash, ½ ounce verdigris, and ½ ounce copperas added, then the mixture strained, and ½ pound rusty steel-filings added. Another (ebony-black) is vinegar, ½ pound; extract logwood, 2 pounds; green copperas, ½ pound; China blue, ¼ pound; nut-galls, 2 ounces. Boil over a slow fire, and add ½ pound iron-rust.

Staith. An embankment on a river where vessels are laden. An elevated railway-track extending over the water for loading coal, etc., into a vessel.

Stake. A weir for fish. A strake of plank.

Stake-head. A wooden arm in the stake-post of a rope-walk, containing pins, to keep the strands apart in laying rope.

Stake-post. An upright wooden post, with mortices for stake-heads, in a rope-walk.

Stammareen (*Eng.*). The helmsman's seat in a Shetland boat.

Stamp and Go! An order to quicken the men at the ropes or at the capstan, intended to make them heave together.

Stanch. Strong; tight. *A stanch vessel*, a strong and water-tight ship. See STAUNCH.

Stanchion. An upright support. *Lifting stanchions* are of iron, and may be raised and fastened to the beam above.

Stand. A small rest or support. *Stand of ammunition*, the projectile, cartridge, and sabot. *Stand of arms*, a rifle, bayonet, belt, cartridge-box, etc. *Stand of grape*, one complete assemblage of grape-shot mounted. *To stand*, to resist. *To stand fire*, to receive an enemy's fire without yielding. *Stand for*, to direct the course towards. *Stand in*, to head in toward land. *Stand off*, to direct the course off shore. *Stand on*, to continue in the same course. *Stand off and on*, to direct the ship's head first to seaward, then shoreward. *Stand out*, to leave a harbor and direct the course seaward. *Stand by a rope*, to attend it, ready to lower or ease it off. *Stand by!* An order to be ready to let sails fall together; to oarsmen to be ready; to men in heaving the deep-sea lead, etc. *Stand by the anchor*, to prepare to let the anchor go. *Stand clear of the cable*, an order to warn all, before the anchor is let go, to keep away from the chains. *Stand from under!* A cry to those about decks to beware of objects falling from aloft. *Stand right under!* A facetious observation, meaning to *stand from under.*

Standard. An inverted knee placed above the deck, such as standards at the bitts, etc. Also, a long pole or upright used in building stages around the ship.

Standard Compass. A compass placed where the local deviation affects it least, and to which the other compasses are referred. It is mounted on a ratchet-stand, or on a tripod, and is usually an azimuth compass.

Standard-deals. Pieces of boards of fir or pine, in form and thickness conforming to a certain trade standard.

Standard-knee. An inverted knee fayed on the deck and against the side.

Standing-backstays. Permanent backstays.

Standing-bevel. A bevel at an obtuse angle.

Standing-bowsprit. A bowsprit permanently fixed in place.

Standing-fid. See FID.

Standing-jib. The jib proper.

Standing-masts. The lower masts.

Standing-orders. Orders or regulations constantly in force.

Standing-part. *Of a hook*, that part opposite to the point. *Of a sheet*, *lift*, etc., that part which is secured to the yard, to the side, etc. *Of a tackle*, that part which is made fast to the block, or to any fixed point.

Standing-pull. A pull on a rope without moving, facing towards the running part, and pulling 2 or 3 feet at a *swig.*

Standing-rigging. The rigging that is permanent, and does not serve to move yards, masts, sails, etc.

Standing-stay. The principal stay, as opposed to the *spring-*, or *spare-stay.*

Standing Warrants (*Eng.*). Officers remaining with a ship in ordinary, as the gunner, boatswain, carpenter, and cook.

Standing Water. Stagnant or still water, where there is neither current nor tide.

Stand-pipe. A supply-pipe to the boiler, so far below the level of the outside water that the pressure may overcome the steam-pressure in the boiler.

Stangs. Poles placed across a stream. Eel-spears.

Stanly, Fabius, Rear-Admiral U.S.N. Fabius Stanly, son of the Hon. John Stanly, was born in Newbern, N. C., December 15, 1815. Appointed midshipman, December 20, 1831; served in the frigate "Constellation," Mediterranean, 1832–34; receiving-ship "Hudson," New York, 1835; sloops "Concord" and "Warren," West Indies, 1835–36; bark "Consort," surveying, 1837; sloop "Falmouth," "North Carolina," 74, Pacific Ocean, 1837–39; "Delaware," 74, Brazil, 1841–43.

Commissioned as lieutenant, 1841; steamer "Union," special service, 1843–44; steamer "Princeton," special service, 1844; sloops "Dale," "St. Mary's," and "Warren," and frigate "Congress," Pacific Ocean, 1846–48; commanded mail-steamer, 1850; commanded sloop "Warren," California, 1853–54; was executive-officer of navy-yard, Mare Island, 1855; commanded transport "Supply," Paraguay Expedition, 1858–59; commanded steamer "Wyandotte," south side of Cuba, 1859–60; commanded receiving-ship "Independence," California, 1861; light-house duty, California, 1862; commanded sloop "Narragansett" in Pacific, 1863–64; ordnance-officer, Mississippi Squadron, 1864; investigating bounty frauds, 1864; commanded "State of Georgia," South Carolina, 1864–65; commanded sloop "Tuscarora,"

Pacific Ocean, 1865–67; rendezvous in Baltimore, 1869.

During the Mexican war was in the Pacific; took part in the capture of California and defense of San Francisco; had a part in the capture of Guaymas; led the advance in storming Fort Cachori; commanded the expedition against Fort Bacoch Vampa,—took it by storm, leading the charge; was in command of the night expedition to spike a battery of guns on its way to Guaymas; passed through the enemy's lines of 1500 men with 30 men, spiked the guns, and fought his way back to the boats (12 miles), bringing off the wounded and prisoners; was commended in the public dispatches from each of his commanding officers (Capts. Craven, Yard, and Commodore Rudd) for his conduct in each of these actions. There were several other less important affairs not mentioned by name, for which he was also commended in the public dispatches from Guaymas by the above-named officers. Was at the capture of Mazatlan,—Admiral Shubrick commanding,—and was assigned the command of the outpost nearest the enemy, who held the approaches to the city, their nightly attacks being so troublesome that two men of straw had to be placed with each sentinel. Was in the battle of Trois, commanding the centre division, which became the rear on the retreat of the rear division. In this action had 1 man killed and 23 badly wounded out of 25 men; was in the action the next day, commanding the artillery at the capture of the village of Trois; received favorable mention in official reports; had frequent skirmishes with the enemy about Mazatlan, in one of which a hand-to-hand contest ensued, in which he received a lance wound in the breast.

In 1860, when in command of the "Wyandotte" at Key West, after consulting with Gen. Meigs, U.S.A., he placed his ship so as to protect Fort Taylor from the threatened attack of the rebels then mustering in force there; was deprived of his command on reporting his course to the Department. Gen. Meigs was also censured, being ordered from Key West.

Was on the coast of Mexico (Pacific Ocean) during the early years of the Rebellion; received the thanks of the State Department for his diplomatic services there; had received the thanks of the Navy Department twice during the Mexican war from two different Secretaries of the Navy.

In 1865, was ordered to report to Admiral Dahlgren, off Charleston, by whom he was ordered to command Fort Johnson; then to arrange and command an expedition up the Santee with Gen. Schemmelfinnig; then to command the expedition of Bull's Bay with Gen. Porter against Charleston, the success of which caused the fall of Charleston. In this expedition commanded 68 guns and 13 field-pieces.

Commissioned as commodore, June, 1870; light-house inspector, 1871–73.

Commissioned as rear-admiral, February 12, 1874. Retired June 4, 1874.

Staple-knee. An iron knee made in the form of a staple, having one arm secured to the deck-beam above and the other bolted to the deck-beam below, with the body secured to the ship's side.

Starboard. The right-hand side; the right side of the ship when looking forward. From the Saxon, *steoran*, to steer, and *bord*, a plank or border. *Starboard the helm*, see HELM.

STAR-BOWLINES, or STAR-BOLINS. Men of the starboard watch were formerly so called.

Star-fish. Sea-animals of the sub-kingdom of *Radiates*, class of *Echinoderms*, and of the order *Asterias*. Star-shaped, spiny-skinned animals, numerous in all seas.

Star-gazer. A spiny-rayed fish, of the family *Trachinidæ*, genus *Uranoscopus*, having its eyes directed upward. A light sail, formerly used above the sky-sails.

Stars, Fixed. Stars which to an observer on the earth maintain their places with reference to each other. Careful observations compared after a lapse of years show that some of them do move; probably none of them are absolutely fixed in space. Stars are classed by their brilliancy. (See MAGNITUDE.) In the whole heavens about 6000 stars may be seen with the naked eye; the number above the 10th magnitude is placed at 200,000; Herschel's 18-inch reflector reveals 20 millions; instruments of greater power reveal yet greater multitudes.

In olden times it was usual to indicate a star by the position it occupied in the constellation; as, the Bull's-Eye, the Lion's Heart, the Belt of Orion, etc. Many of the brighter stars have names of Latin, Greek, or Arabic derivation; as, Regulus, Sirius, Benetnash, etc. In 1604, Bayer published star-maps in which the stars were indicated by the letters of the Greek alphabet, the brightest in each constellation being α, the next β, the third γ, and so on. When the 24 letters were exhausted in designating the stars he used the Roman letters, and then numbers. The letters do not now always give the exact order of brightness.

Several catalogues of stars have been made,—the first by Hipparchus, B.C. 128, contains 7026 stars.

The polariscope shows that the stars are luminous bodies. The stellar light, analyzed by the spectroscope, indicates elements in the stars identical with those in the sun and on the earth, together with others utterly unknown.

Sirius is computed to be, as a centre of light and heat, 394 times larger than the sun. *α Centauri*, the nearest of the fixed stars, is 21 millions of millions of miles distant; Polaris is 292 millions of millions of miles distant, and the time required for the passage of light from this star to earth is about 48 years. *Periodic stars* increase and diminish in brightness at regular intervals; about 100 are known, having periods varying from a few days to many years. The most remarkable periodic star is *β Persei*, in the head of Medusa; it is of the 2d magnitude for $2^{d}\ 13^{h}$; it then changes, in 3½ hours, to the 4th magnitude; in 3½ hours more it regains its former brightness. Stars which appear single to the naked eye are sometimes resolved into two or more by the telescope. The components of a *double star* may be only apparently near; in certain cases one of the components describes an orbit about the other. In the latter case the star is known as a *physically double* or *binary* star. Single stars show great variety of color, running through shades of red, yellow, blue, and green; some stars have changed color. Sirius was formerly red; afterward it shone with purest white, and of late has a greenish tinge. Aldebaran, Antares,

and Betelgeuse are red; Arcturus is orange; Capella, bluish. Many fixed stars have a small proper motion; hence it appear that the solar system is moving through space. The motion is toward a point in the group Hercules, and is probably about a very remote centre not yet known.

Start. A point of land. A point of departure. The place a whale is expected to rise, after being struck. To move weights. To empty out liquids. *To start bread*, to pour it out from bags or barrels, and stow it in bulk. *To start a butt*, to loosen a plank at the butt, by the working of the ship. *To start a rope*, to ease it off a little. *To start the men*, to hurry them on deck,—formerly, by a vigorous use of a rattan or rope's-end.

START-HAMMER. A hammer with a small head, used to drive a bolt into the wood.

START-BOLT, or STARTING-BOLT. A bolt used to drive out another bolt. A drift-bolt.

STARTING-BAR. A bar by which the valve-gear of a steam-engine is manipulated by hand when starting the machine in motion, either for going ahead or backing.

STARTING-VALVE. A small auxiliary valve for admitting steam to a cylinder of an engine when starting, used to avoid manipulating the main valves by hand. Sometimes called a *tail-valve.*

STARTING-WHEEL. A wheel, worked by hand, by which the go-ahead or backing motion of the valve-gear of a steam-engine is thrown into action at will, thereby starting, stopping, or reversing the motion of the engine.

Stash it there! An old cry to enforce silence.

State-room. A small room in the cabin or wardroom of a man-of-war, or in the saloon of a merchantman, for the private use of an individual. In the wardroom the state-rooms are occupied, on the starboard side by line-officers, and on the port, by staff-officers. They are allotted according to rank, the senior officer occupying the forward room. In vessels having the wardroom forward, the senior officers are entitled to the after rooms.

Station. The allotted place of each person on board. These are designated on the station- and quarter-bill. *Cruising station*, the locality in which a ship habitually cruises. The ships of the U. S. navy are distributed among 5 stations, viz.: A. The *North Atlantic*, or *Home Station*, comprising those ships on the east coast of North America, extending east to Bermuda and south to the equator. B. The *South Atlantic Station*, comprising the shores of South America and Africa bordering on the Atlantic, south of the equator, and the waters between. C. The *European Station*, comprising the European, Mediterranean, and African coasts, as far south as the equator. D. The *Pacific Station*, comprising the west coasts of North and South America and the islands as far as Australia and the Sandwich Islands. E. The *Asiatic Station*, comprising the coasts of Asia and Africa, from Behring's Strait to the Cape of Good Hope, with all the islands contiguous. *Shore-station*, see SHORE. *Every man to his station and the cook to the fore-sheet!* calls all idlers in merchantmen. *To station*, to post or place a man in a particular place, as a sentry on his post, a hand by the fore-sheet, etc. *To station look-outs*, is to send them to their allotted places

STATION-BILL. A bill containing a list of the crew, with their stations and duties for all evolutions. See WATCH-, QUARTER-, AND STATION-BILL.

STATIONER (*Eng.*). One who has served long in any particular station.

STATION-POINTER. An instrument used in maritime surveying, to lay down points on a chart from angles previously measured. Three arms move about a central pivot, and arcs are attached graduated so as to set these arms to any angles, and by this means find the point desired, and lay it down on the chart.

STATIONS FOR STAYS! A preliminary order in tacking, or box-hauling ship, to direct the men to their stations.

Staunch. A flood-gate in a river, so contrived as to form a head of water, and float lighters over shallows.

Stave. To break a hole in a boat. To drive in the head of a cask. *Stave off*, to boom off, or to push off with a small spar. Figuratively, to cause to be deferred.

Stay. A strong rope, leading from the head of any mast, forward. A support to a davit,

* A name given by modern astronomers to express the extreme beauty of this double star (orange and green), viewed with a good telescope.

bumpkin, etc. A stay-tackle. A bar or rod confining two or more parts of a structure or machine to an invariable relative position. Tie-bars or rods are sometimes called *stays.* The stays of a ship that lead forward to the centre line of the ship are *fore-and-aft stays.* Those leading aft to the ship's side are *backstays.* The various stays will be found described under their headings. A *steamer's stay* is an iron rod uniting the paddle-boxes. A *jumper-stay* is a main-stay which comes to the side of the ship. These are necessarily used in steamers, where the funnel interferes with their leading straight. *To stay,* to support a mast by setting up the rigging. To tack, to bring the ship's head to the wind in going about. *In stays,* or *hove in stays,* in the act of going about. *To refuse stays,* to fail to tack. *To miss stays,* to fail in an attempt to put the ship about.

STAY-APEEK. See APEEK.

STAY-BAR, or STAY-ROD. Strong bars or rods supporting the top of a furnace.

STAY-BOLT. A short *stay* or *bolt* for supporting the flat surfaces of the shells, fire-boxes, etc., of a steam-boiler.

STAY-HOLES. Holes in the luff of a stay-sail, for the lacing, rings, or hanks that fasten it to the stay.

STAY-ROD. See STAY.

STAY-SAIL. A triangular or trapezoidal sail hoisted on a stay.

STAY-SAIL-NETTING. A rope or canvas receptacle on the bowsprit for the fore-topmast stay-sail.

STAY-SAIL-STAY. The stay on which a stay-sail is set. Sometimes, as in the case of the *fore-storm stay-sail,* this is a separate stay, only gotten up in time of need. When on the *standing-stays,* the *port-* or *spring-stay* is preferably used for a stay-sail. A stay-sail is fastened by its tack, and hoists along the stay, being confined to it by wooden or iron thimbles, or rings, by rope or hide hanks, or by bridles or lacings toggled into the stay-holes, or into eyes.

STAY-TACKLE. Any tackle put on a stay for hoisting out or moving weights. A stay-purchase, a tackle used in setting up a stay. Tackles hooked to the ends of the triatic-stay, used in hoisting boats' anchors, etc., in conjunction with the yard-tackles.

Steady! An order to the helmsman to steer as the ship heads.

Steady-fast (*Eng.*). A hawser carried out to some fixed object, to keep a ship steady in a tide-way, or to make sail from.

Steal. To gain a ratline or two in going aloft, while waiting for the order. To pick up the sail before the order to furl is given. To gain distance ahead in light airs.

Stealer. A plank introduced at the stem or stern between curved edges and straight-edged planks.

Steam. An elastic vapor into which water is converted when heated to the boiling-point. This point depends on the amount of salt in the boilers, and for fresh water is 212° F. Advantage is taken of the elasticity of steam in the steam-engine, where its expansive force is transferred to other mechanical powers through the piston. *High-pressure steam* is that whose temperature is far above the boiling-point. *Low-pressure steam* is that at the boiling temperature. *Saturated steam,* or *wet* steam, is that which holds water in mechanical suspension. *Superheated, surcharged,* or *anhydrous* steam is that which is heated after separation from the water, until all the water held in suspension is vaporized. *Dry steam* holds but little water in suspension. *The mechanical equivalent of steam* is the amount of force it exerts to raise 1 pound of water, 1° F. in temperature, and this is 772 foot-pounds. The conditions affecting steam vary with its temperature, but at 212°, saturated steam exerts a pressure of 14.7 pounds per inch. Its total heat is 1.146°, its latent heat being 965.2°; its weight per cubic foot is .038 pound, and the volume of 1 pound is 26.36 cubic feet. The volume of 1 cubic foot of water after evaporation is 1642 cubic feet, at a temperature of 212°.

STEAMBOAT. A boat propelled by steam. The term is generally applied to river and coasting steamers.

STEAM-BOILER. See MARINE STEAM-BOILER.

STEAM-BOILER ALARM. An alarm, to tell when the water is low in the boiler.

STEAM-BOX, STEAM-CHAMBER, STEAM-CHEST, STEAM-DOME, STEAM-CHIMNEY. Synonymous terms for a receptacle of steam from a boiler; the object of the device is to temporarily check the velocity of the steam so that water held in suspension, either by condensation or being drawn from the boiler by induction, may have time to precipitate before passing to the engine. A *steam-chimney* is usually an annular steam-space surrounding the lower part of the smoke-pipe, by which arrangement the steam is dried and somewhat superheated. The term *steam-chest* is frequently applied to the valve-chest of an engine.

STEAM-CASING. See STEAM-JACKET.

STEAM-CUTTER. A steamboat, smaller than a launch.

STEAM-GAUGE. An instrument for indicating steam-pressure by means of a dial and index, or a plain graduated scale. There are numerous devices, nearly all depending for their action upon the resilience of metal or the weight of a column of mercury. The latter, only, can be considered reliable.

STEAM-GUN. A gun in which balls are propelled by the force of steam. Leonardo da Vinci describes one in a manuscript of 1500. Van Etten, in 1629, also described one. One was made and shown in England in 1824. Bessemer proposed to throw balls from the nozzle of a steam-pump, or fire-engine. Wood and Lay devised a steam-gun to be used under water, but it was not successful. The elastic force of steam is not a constantly increasing succession of shocks, such as is necessary in a gun, and will probably never be successfully used in this connection.

STEAM-HOIST. A steam hoisting-machine used in navy-yards for various purposes.

STEAM-JACKET. A device by which a steam-cylinder is surrounded by a thin film of live steam; the object being to prevent the condensation, due to various losses of heat, of a large quantity of *working* steam within the cylinder, and the consequent loss of latent heat, by the expenditure of a smaller quantity of heat from steam of higher temperature.

STEAM-LAUNCH. A launch fitted with steam-power, furnished to most modern men-of-war. *Steam torpedo-launches* are for the purpose of

exploding torpedoes under the enemy's bottom, and are long, narrow, and flat. See TORPEDO-LAUNCH.

STEAM-PIPE. A pipe for conducting steam from a boiler to an engine, heater, evaporator, or other apparatus where it performs work.

STEAM-PORT. An opening for the admission of steam to a cylinder, and, except in a few special devices, for its expulsion therefrom after having performed its work.

STEAM-ROOM. The space contained within a steam-boiler for the accumulation of steam above the water-level.

STEAMSHIP. Any large vessel driven by steam. See STEAM-VESSEL.

STEAM-TOE. A cam-shaped, oscillating arm or lever, forming part of some kinds of valve-gear, for opening and closing the steam-valve of an engine, as in the Stevens cut-off.

STEAM-TUG. A small steam tow-boat.

STEAM-VESSEL. A vessel propelled by steam-power. The first attempt to propel vessels by steam-power was made at Barcelona, by Blasco de Garay, in 1542, and various attempts were made during the 16th, 17th, and 18th centuries, but it was not until the beginning of the present century that successful *steamboats* were built, Fitch running a boat on the Potomac in 1787, Symington, the "first practical steamboat," the "Charlotte Dundas," in 1801, and Fulton, the "Clermont," first to regularly engage in traffic, in 1802.

STEAM-WHISTLE. An apparatus attached to an engine, through which steam is discharged, making a shrill sound by striking the edges of a metal cup, causing it to vibrate.

STEAM-WINCH. A hoisting-machine, or windlass, which is made to revolve by a crank connected with the piston of a small cylinder. They are extensively used on modern men-of-war, for various purposes.

Steedman, Charles, Rear-Admiral U.S.N. Native of Charleston, S. C. Appointed midshipman in the navy, April 1, 1828; first duty at the New York Navy-Yard; served in the West Indies as midshipman in the sloops-of-war "Natchez" and "Fairfield," and schooner "Grampus."

Promoted to passed midshipman, January 14, 1834. In the Mediterranean on board of the frigates "Constitution" and "United States" and schooner "Shark" in the years 1836–38; and in the West Indies on board the "Macedonian" up to 1840,—the last six months as acting lieutenant.

Promoted to lieutenant, February 25, 1841; served in the brig "Dolphin" on the Home Station and West Indies; invalided and sent home 1842; coast survey, 1843–44; served in the West Indies and Gulf of Mexico on board of the "St. Mary's," 1845–47; commanded the 8-inch gun in the naval battery at the bombardment of Vera Cruz, and commanded the "St. Mary's" launch in an attempt to surprise and capture Mexican gunboats inside of Tampico bar; attached to Naval Observatory from latter part of 1847 to first of 1849; served on board frigate "Cumberland" in the Mediterranean, 1850–51; attached to Naval Observatory, 1853–55.

Commissioned as commander, September 14, 1855; special duty in Washington, 1857–58; revising signal code and framing station-bills for ships of the navy; commanded brig "Dolphin," Paraguay Expedition, 1859–60, and was left in command of Brazil Squadron when Flag-Officers Shubrick and Forrest returned home, remaining in command for nine months until the arrival of Flag-Officer Sands; returned home in December, 1860. At breaking out of the Rebellion was on leave; volunteered to Admiral Dupont for any service, and was by him sent to take command of the Baltimore Railroad Company's steamboat "Maryland"; kept communication open between Havre-de-Grace and Annapolis until the railroad bridges were repaired and communication opened between Baltimore and Philadelphia; was first to telegraph from Havre-de-Grace to Gen. Patterson that Gen. Butler had landed at Annapolis with Massachusetts regiment and Seventh New York Regiment, and had opened communication with Washington; in 1861, ordered to join Commodore Foote on the Mississippi; soon detached and ordered to take command of the "Bienville"; attached to Port Royal Expedition under Flag-Officer Dupont; led the second column in the attack and capture of Port Royal; brought North, in the "Bienville," Flag-Officer Dupont's dispatches reporting the capture; after this assisted in blockading the coast of Georgia in the "Bienville," and participated in the capture of all the ports on that coast south of Savannah; returning North, was detached from the "Bienville" and ordered to the "Paul Jones"; joined Admiral Dupont's squadron with the "Paul Jones" and other gunboats; engaged Fort McAllister, on the Ogeechee River, in August, 1862; on the 17th September following engaged and silenced the batteries at St. John's Bluff, on the St. John's River, Fla.; considering it necessary to have troops to co-operate in capturing the forts and getting possession of the river, applied to Admiral Dupont for the same on the 30th of same month; with the co-operation of Gen. Brannon captured the forts on St. John's Bluff, and with the gunboats opened and held the St. John's River to Lake Beaufort.

Commissioned as captain, September 13, 1862. Transferred to the steam-frigate "Powhatan," and employed in her blockading off Charleston for several months; with the "Powhatan" towed the captured ram "Atlanta" to Philadelphia; soon after was detached and took command of the "Ticonderoga"; in her was employed on various detached service; returned in her in November, 1864, with engines disabled from an unsuccessful search of the rebel vessel "Florida," on the coast of Brazil; volunteered to join Admiral Porter's command; vessel temporarily repaired; joined the admiral and participated in the two attacks and capture of the forts at the mouth of the Wilmington River, December, 1864, and January, 1865; after the fall of those forts joined Admiral Dahlgren's squadron off Charleston; the "Ticonderoga" being unfit for service, was ordered to Philadelphia for repairs; so soon as she was repaired, proceeded, November, 1865, to the Mediterranean and joined Admiral Goldsborough's European Squadron.

Promoted to commodore, July 25, 1866; soon after exchanged commands with Capt. Wyman, of the "Colorado"; returned home in the "Colorado," September, 1867; on special duty, 1868–69, and commanding Boston Navy-Yard, 1869–72.

Commissioned as rear-admiral, May 25, 1871. Retired September 24, 1873.

Steel. See Iron and Steel.

Steel-bronze. A mixture of steel, tin, and copper, used in making guns. It was patented in 1870 in Boston, and is extensively used in Austria for the manufacture of light guns.

Stembel, Roger N., Rear-Admiral U.S.N. Born in Middletown, Md. Appointed from Ohio, March 27, 1832; attached to schooner "Porpoise," West India Squadron, 1832–33; Naval School, New York, 1834–38.

Promoted to passed midshipman, June 23, 1838; attached to frigate "Brandywine," Mediterranean Squadron, 1840–42.

Commissioned as lieutenant, October 26, 1843; coast survey, 1844–47; sloop "Levant," Home Squadron, 1849–50; sloop "Jamestown," Brazil Squadron, 1851–53; special duty, Washington, 1855–57; steam-frigate "Mississippi," East India Squadron, 1857–59; special duty, Cincinnati, 1861.

Commissioned as commander, July 1, 1861; Mississippi Flotilla, 1862; engagement at Lucas Bend, September 9, 1861; Belmont, November 7, 1861; Fort Henry, February 6, 1862; bombardment and capture of Island No. 10, Mississippi River, from March 16 to April 7, 1862; engaged near Fort Pillow with rebel rams, May 10, 1862, besides several minor affairs, while attached to Mississippi Flotilla, from August, 1861, to May, 1862; wounded near Fort Pillow, May 10, 1862, in engagement with rebel rams; waiting orders, 1863; rendezvous, Philadelphia, 1864; special duty, Pittsburgh, 1865.

Commissioned as captain, July 25, 1866; commanding steam-sloop "Canandaigua," European Squadron, 1866–67; commanding naval rendezvous, Boston, 1869–70.

Commissioned as commodore, July 13, 1871; commanding North Pacific Fleet, 1872. Retired December 27, 1872.

Commissioned as rear-admiral, February 2, 1875.

Steep-to. Said of a bold shore, near to which vessels may approach.

Steep-tub. A large tub for soaking salt-provisions.

Steer. To direct or govern a ship by the motions of the rudder. It requires considerable skill to steer well, the helmsman being compelled not only to watch the compass and the ship's head, but also to feel and anticipate the motions of the ship in a sea-way. To *steer large* is to use much helm, or to steer loosely, and also to go free. To *steer small* is to steer with little helm, or small movements of the wheel. To *steer the course* is to lay the course with a free or fair wind.

Steerage. The act of steering. The effect of the helm on a ship. (*Eng.*) That part of the ship below the quarter-deck and before the cabin bulk-head of a man-of-war. (*Eng.*) The cabin of the middle-deck of a three-decker. The forward part of the lower-deck of a passenger-steamer or ship. That portion of the berth-deck of a man-of-war just forward of the ward-room, and furnished with lockers, mess-tables, and sometimes with berths.

Steerage-officer. An officer living or messing in the steerage. Steerage-officers in the U.S. navy are clerks, midshipmen, cadet-midshipmen, mates, cadet-engineers, ensigns when not in charge of a watch and division, and all officers ranking with ensign.

Steerage-passenger. A second- or third-class passenger in a merchant vessel.

Steerage-way. The motion of the vessel through the water, sufficient to cause her to obey the helm.

Steering Apparatus. Machinery giving increased power for the management of the rudder. Many forms have been invented, and some are successfully used. *North's steering apparatus* consists of a wheel turning a horizontal shaft on a table, geared to a vertical shaft on which is a drum with a chain fastened to it. The ends of this chain connect to a quadrant on the rudder-head, and motion is thus given to the rudder. *Jackson's* is a right- and left-handed screw on the shaft of the wheel, on which sleeves move, attached to levers. These levers move the tiller, as the wheel works the screws. These forms of steering gear are generally used as preventer-gear, situated aft, while a wheel situated forward steers the ship ordinarily, by means of rods or chains running aft to the tiller. These are now superseded in large ships by steam- or hydraulic gear. The steam-gear is of various patterns. That used in the English navy has two small engines connected with the tiller, whose valves are controlled by a light steering-wheel. Another English apparatus consists of a pair of cylinders acting by gearing on a worm-wheel, to the shaft of which the steering-barrel is keyed, and a chain on this barrel moves the tiller. Automatic gear stops the engine when the rudder is hard over. *Sickles's gear*, on the "Miantonomoh," consists of two cylinders moving a crank attached to the shaft of the steering-barrel. Wire-rope is wound on this barrel, which is so made that double the leverage is effected when the helm is hard over. A hand-wheel on the same shaft moves the engine-valves by a cam and yoke, and the engine stops when the shaft reaches the same point to which the hand-wheel has been turned. The *Brotherhood apparatus* uses three cylinders, and lays the tiller at any angle.

Hydraulic steering-gear has been used in some large modern ships, and is very successful. In it a small tiller opens the valves of the hydraulic pump. Other steering-gear connects with the propeller.

Steering-propeller. A propeller so contrived that the ship is steered by it without a rudder. The first attempt to so control a ship was made by Stevens, who thought that he could control a vessel by right- and left-handed screws, but these do not act sufficiently well. Other devices are in use, the Fowler and Mallory wheels being the most successful. *Hunt's steering-propeller* changed the angle of the shaft of the screw by a small hand-wheel, connected to it by gearing from above.

Steering-sail. A studding-sail.

Steering-signals. Signals made by an electric apparatus connected with the helm, so as to indicate the position of the rudder and its movements. Several such apparatus have been devised, but none are in general use. Signals from the commander-in-chief prescribing the courses to be steered.

Steering-wheel. The wheel by which the

tiller is moved. The ordinary steering-wheel is a common wheel whose spokes project beyond the rim, and whose hub is prolonged to form the barrel. On this barrel is wound the wheel-rope. By moving the wheel to the right or left, the opposite rope is wound on the barrel, thereby moving the tiller to that side. In men-of-war the wheel is ordinarily aft, just forward of the mizzen-mast, but in some modern ships it is placed in a shot-proof house on the forward part, or near the middle of the deck, or even on the bridge or hurricane-deck. Duplicate wheels are often used in different positions. In merchant steamers wheels are generally placed in pilot-houses forward, and connect by chains or rods with the tiller. Wheels are also used with screw- and steam-steering-gear, as described in STEERING APPARATUS, which see.

STEERSMAN. A helmsman.

Steeve. To elevate at an angle any spar, as a bowsprit. To stow cargo in the hold by a *steeve*, or by a jack-screw. The angle which a spar, as the bowsprit, makes with the horizon. A long derrick or spar, with a block at one end, used in stowing cargo.

Stellwagen-cup. A sounding-cup devised by Lieut. Stellwagen, U. S. navy, for bringing up portions of the bottom.

Stem. The main timber at the forward end of the ship, formed by a combination of several pieces into a curvilinear figure. Its lower end scarfs into the keel, and it receives the ends of the planking around the bow. *To stem*, to make headway against a tide or current.

STEMSON, or STEM-KNEE. A piece or pieces of curved timber wrought on the after part of the apron, on the inside of the ship. Its lower end scarfs into the keelson, its upper end being continued as high as the middle or upper deck.

Step. A step, generally, is a framing in wood or iron, which is intended to receive an upright shaft. *To step*, to fix a boat's mast or a lower mast in position. At the present time, the fore- and mainmasts are stepped in cast-iron mast-steps, made to fit down over the main keelson, with a broad flange on the sister keelsons, to which they are secured. The mizzen-mast steps in a piece of live-oak timber, scored down over the berth- or orlop-deck beams, to which it is secured. *Steps of the side*, pieces of oak, worked with moldings, and fastened on the ship's side at the gangway, for the convenience of ascending and descending when the accommodation-ladder is unshipped.

STEPPING-LINE. The bearding-line, or the line of the top of the rabbet on the dead-wood on which the frame-timbers step.

Stephenson-link. A part of the valve-gear of a steam-engine by which the motion from either the go-ahead or backing eccentric, or a combined motion of the two, is transmitted to the valves, without "unhooking" or disconnecting. The engine can be stopped by bringing both eccentrics into nearly equal action upon the valves, which is accomplished by placing the link in mid-position by means of the reversing-gear; and a *variable cut-off* within narrow limits may be effected by setting the link in various positions by the same means.

Sterlet. A species of sturgeon (*Acipenser ruthenus*), found in the Caspian Sea, and its rivers, from whose roe is made the finest caviare.

Stern. The whole after part of the ship, as the forward part is called the bows, but more especially that part of the ship which is bounded by the main-transoms and the counter-timbers.

STERN-BOARD. The backward motion of a ship, resulting from negligence at the helm, or bad seamanship; or the effect of an intentional manœuvre, as that of throwing sails aback suddenly to avoid a danger. *To make a stern-board*, to fall astern in tacking.

STERN-BOAT. A boat carried astern.

STERN-CHASE. A chase where one vessel follows the other in her wake, both steering the same course. A proverb makes it "long but sure."

STERN-CHASERS. Guns firing directly aft.

STERN-DAVITS. Davits to which a stern-boat is hoisted.

STERN-FAST. A rope confining the stern to a wharf, or buoy.

STERN-FRAME. The stern-post, transoms, and fashion-pieces, bolted together, constitute the stern-frame.

STERN-GALLERY. A gallery or walk formerly built across the square sterns of large ships. On three-deckers there were two.

STERN-KNEE. A large knee which forms the lower piece of the dead-wood aft and connects the stern-post to the keel, the arm being securely bolted to the stern-post and the body to the keel.

STERN-LADDERS. Rope ladders hung on either quarter, for convenience in ascending. At sea they have long laniards trailing astern.

STERNMOST. Farthest in the rear.

STERN-PORTS. Ports made in the stern of the ship, so that guns may be used as stern-chasers.

STERN-POST. A long, straight piece of timber whose lower extremity is securely fastened and tenoned into the keel, and whose top is secured to the main-transom. It receives the ends of the planking at the after end of the ship. In iron ships it is simply a bar of iron bolted to the keel, to which the plates at the after end are riveted.

STERN-SHEETS. The after part of a boat, between the after thwart and the coxswain's box.

STERNSON. The upper piece of curved timber uniting the dead-wood to the stern-post at the upper end in wooden ships.

STERN-WALK. A stern-gallery.

STERN-WAY. The opposite of headway. Motion backward, or astern.

Stevedore. A stower. One employed to stow the hold of vessels, or to unload from the hold.

STEVEDORE'S-HOOK. An iron hook with a handle, to hook in bales, etc.

Stevens, Thomas Holdup, Commodore U.S.N. The subject of this sketch was born in Charleston, S. C., February 22, 1795. Losing his parents early in life, Gen. Daniel Stevens, an eminent citizen of that State, and the first mayor of that city, became specially interested in him, and eventually adopted him. Entering the navy as a midshipman, January 16, 1809, he was ordered to the Charleston Station, upon which duty he remained until ordered to the sloop-of-war "John Adams," on board of which vessel he remained until the fall of 1812, when, as an acting lieutenant, he accompanied Commodore Chauncey to Sackett's Harbor, where a naval force was being organized for co-operation with the army on the frontier, and to operate against the floating force of the enemy upon the Northern lakes. Shortly after reaching Sackett's Har-

bor he was assigned to duty on the Niagara frontier with Capt. Angus, and was with that officer in the desperate night attack upon the enemy's works opposite Black Rock. Of his conduct upon that occasion Capt. Angus reports: "I was, immediately after landing, joined by the truly brave Holdup Stevens, who behaved himself like a gallant and valuable officer." And again: "As for the gallant Wragg, Dudley, and Holdup Stevens, their conduct speaks for itself." In recognition of this splendid service he was commissioned a lieutenant in the early part of January, 1813. (For further notice of his war-service see Cooper's "Naval History.") Congress voted him a silver medal for Lake Erie, and the citizens of Charleston, S. C., presented him a sword. Remaining upon the lakes as executive-officer of the "Niagara" until November 19, 1814, he was then ordered to the frigate "Java," fitting out under Commodore O. H. Perry for a cruise in the Mediterranean. In 1819–20 he was attached to the frigate "Constellation," and for two years subsequently was attached to the navy-yard, New York, under command of Commodore Chauncey. When the Mosquito Fleet under Commodore Porter was being fitted out for the suppression of piracy in the West Indies, he was ordered to report for duty to that officer, and was first assigned to the command of the "Asp," subsequently to the command of the schooner "Jackal," and later to command the schooner "Shark," in which vessels he rendered efficient and valuable service, and added largely to his brilliant reputation. In March, 1825, he was promoted to a master commandant, and in 1827-29 was the executive-officer of the Washington Navy-Yard, remaining, upon the death of Commodore Tingley, temporarily in command. Upon the expiration of this term of service he was ordered to the command of the sloop-of-war "Ontario," one of the vessels comprising the Mediterranean Squadron, under the command of Commodore James Biddle, and upon various occasions was intrusted by that distinguished officer, whose confidence he possessed to an eminent degree, with duties of a highly responsible, grave, and delicate character. Returning to the United States with the respect, esteem, and affection of all with whom he had been associated, he was ordered to the command of the naval rendezvous at Boston, where he remained, popularizing the navy and himself through his rare social gifts and high qualities, until promoted to a captain, in 1836. In 1840–41 he commanded the navy-yard and station at Washington, D. C., with signal success and ability. While upon this duty a very serious difficulty occurred between the late Commodore M. C. Perry and Admiral F. H. Gregory, which was only prevented from a mortal issue through the earnest and untiring efforts and friendly interference of that gifted and incomparable officer, Commodore Charles Morris, and the chivalric officer of whom we write.

Cut off in the vigor and bloom of manhood, with the past an earnest of his future, we have just reason to believe that in the stormy times in which we have recently lived, had his life been spared, he would have been, through the force of his character and his high professional qualities, a prominent actor and a conspicuous leader.

The *National Intelligencer*, of Washington, at that time edited by Mr. Seaton, published the following beautiful tribute to Commodore Stevens at the time of the publication of the General Order announcing his death:

"The Naval Order which appears to-day will announce to our readers the decease—sudden and unanticipated as it is afflicting—of Commodore Thomas Holdup Stevens, of the navy. In the meridian of life, and in the enjoyment of the highest health, he retired to bed on Wednesday night, and before morning the angel of death had stricken him from the number of the living. We know not when any instance of those solemn dispensations which Providence orders, as it were, as admonitions of the uncertain tenure of existence, has struck upon us more painfully.

"Open-hearted, frank, and generous, we know not a man who made his way so directly to the affections of all to whom he became known as this gallant and lamented officer; and proportionably keen is the sorrow for his loss and the sympathy which is universally felt for his large and estimable family.

"Commodore Stevens was a native of Charleston, S. C., and entered the navy in 1809, at the early age of fifteen. Young as he was, he had distinguished himself in the war of 1812, even before Perry's brilliant victory on Lake Erie, and he commanded one of the vessels in that ever-memorable battle. As a man, he was without reproach, and as an officer, he was regarded as one of the brightest ornaments of the navy in peace, as he had been one of its most gallant sons in war."

Stevens, Thomas H., Rear-Admiral U.S.N. Born in Connecticut. Appointed from Connecticut, December 14, 1836; attached to razee "Independence," Brazil Squadron, 1838–41.

Promoted to passed midshipman, July 1, 1842; surveying duty, Gulf of Mexico, 1842–43; steamer "Michigan," on the lakes, 1843–44; naval storekeeper, Honolulu, 1845–48; Naval Station, Sackett's Harbor, New York, 1849.

Commissioned as lieutenant, May 10, 1849; attached to steamer "Michigan," on the lakes, 1849–51; coast survey, 1852–55; steam-frigate "Colorado," Home Squadron, 1858–60; commanding steam-gunboat "Ottawa," 1861–62; participated in the engagement with the rebel fleet at Port Royal, November 4, 1861; and engagement with Forts Beauregard and Walker, November 5, 1861; battle of Port Royal and capture of Forts Beauregard and Walker, November 7, 1861; battle of Port Royal Ferry, January 1, 1862; engagement with Tattnall's rebel fleet, February, 1862; capture of Fort Clinch and the towns of Fernandina and St. Mary's, and steamer "Darlington," March 3, 1862; engagement with enemy's riflemen on the St. Mary's River, March 6, 1862; during the months of March and April, 1862, Lieutenant Stevens was in command of the first expedition up the St. John's River, which captured Forts Steele and Finnegan, with their guns, etc., and the towns of Mayport, Jacksonville, Magnolia, and Pulaski, and yacht "America."

Commissioned as commander, July 16, 1862; commanding steamer "Maratanza," North Atlantic Blockading Squadron, 1862; present at the battle of West Point, and in command of the first naval expedition to Cumberland and White

House to open the river for and support the advance of Gen. McClellan, May, 1862; present at demonstration against Petersburg and battle of Malvern Hill, June, 1862; on July 4, 1862, the "Maratanza," under the command of Commander Stevens, captured the rebel gunboat "Teazer"; commanding ironclad "Monitor," North Atlantic Blockading Squadron, 1862; while in command of the "Monitor," covered the flank of McClellan's army on the James River and the rear in his withdrawal from the Peninsula; commanding steamer "Sonoma," West India Squadron, 1862–63; capture of schooner "Clyde," steamer "Victoria," brigantine "Atlantic," bark "Springbok," steamer "Virginia," and chase of rebel privateer "Florida" for 34 hours; commanding ironclad "Patapsco," South Atlantic Squadron, 1863; while in command of "Patapsco," participated in engagement with Fort Morgan, August 22, attack on Fort Sumter, August 23, and engagement with Fort Moultrie, Battery Bee, and adjacent batteries, in command of 4 monitors, August 31; on September 1, demonstration against Fort Sumter and obstructions; September 6, engagement with Forts Wagner and Gregg and capture of the same; September 7, demonstration against Fort Sumter and obstructions, and engagement with all of Sullivan's Island batteries; September 8, engagement with Sullivan's Island batteries; in command of boat assault on Fort Sumter on the night of September 8; bombardment of Fort Sumter, from October 25 to November 4, inclusive; commanding steam-sloop "Oneida," Western Gulf Blockading Squadron, 1863–65; operations before Mobile, from July 1 to August 3, 1864; to enable Commander Mullany (now rear-admiral), who had volunteered for the occasion, to participate in the fight, Stevens consented to take the double-turreted monitor "Winnebago," and Mullany was assigned to the "Oneida" (by this arrangement both these officers commanded fighting ships); commanded monitor "Winnebago" in engagement with Fort Powell, driving off reinforcements and supplies, August 4, and in battle of Mobile Bay, and capture of rebel ram "Tennessee" and fleet, and at capture of Forts Powell and Gaines; bombardment and capture of Fort Morgan; while in command of "Oneida," May 13, 1865, off Boca Chico, Texas, covering left flank of the army from apprehended attack; present at the ratification of the agreement for the surrender of the trans-Mississippi army by Gens. Curtis, Smith, and Magruder; in command of Texas division of Gulf Squadron, July, 1865; in August, returned to New York in command of the "Oneida."

Upon the occasion of his leaving the squadron, the following letter was addressed him by the late Admiral Dupont:

"I cannot permit you to leave without expressing my regret at your withdrawal from my squadron, having ever found you prompt, energetic, skillful, and brave in all the duties pertaining to your command. Your operations on the St. John's River, as senior officer of the naval forces which took possession of those waters, were attended by circumstances requiring judgment and discretion, both of which you exhibited in a manner highly satisfactory to me.

"I am, sir, respectfully, your obedient servant,
"S. F. Dupont."

Upon being relieved of the command of the "Monitor," then in Hampton Roads, the present rear-admiral, John Rodgers, wrote as follows:

"In all the time of our companionship on duty you have evinced courage and coolness. In our reconnoissance of the forts at Hilton Head previous to the grand attack, in the grand attack in which they were taken, in the Cooper River, in the Appomattox, with your vessel aground under very trying circumstances, you have exhibited the characteristics of a valuable officer. I have not cited occasions of which I have only heard, but of which I have been mindful, where your conduct has received the warmest praise. Everywhere you have shown yourself a dashing, zealous officer."

Rear-Admiral Charles Wilkes, in a letter to the Secretary of the Navy, in reference to Capt. Stevens, writes,—

"I have had many and favorable opportunities, having been associated with him (Commander Stevens), and he served under my command in the James River, and in the West Indies, most of the time under my immediate observation. His patriotism is beyond doubt; his ability as an officer is second to none in the navy; he has at all times given me on duty entire satisfaction in the performance of his duties, and the zeal with which he executed them. I think him a high-toned officer and a gentleman, and know him to be an ornament to the service. His duties engrossed his whole attention; ever ready and prompt in their execution, winning my entire satisfaction and confidence in his willingness, activity, and ability in the execution of orders. His command was always held ready for duty, and through his example, energy, and good management he fulfilled many orders, overcoming great difficulties he had to encounter. He is brave and chivalric; no officer could have shown more attachment to the Union cause during the late war, and none exerted themselves more to maintain and restore the Union, and uphold the honor of our flag."

Commissioned as captain, July 25, 1866; light-house inspector, 1867–70; commanding frigate "Guerriere," European Squadron, 1870–71.

Commissioned as commodore, November 20, 1872; commanding navy-yard, Norfolk, Va., 1873–76. While on this duty, assigned by the President, at the request of the governor of Virginia, as member of the U. S. Advisory Board of Harbor Commissioners of Norfolk and Portsmouth; continued upon same duty after being relieved as commandant of the yard, upon expiration of term, and also employed at present as president of board for examination of and report on "Puritan." Special duty, Norfolk harbor, 1876–80.

Commissioned as rear-admiral, October 27, 1879; commanding Pacific Squadron, 1880.

Steward. A person employed on board ships to provide for the table, superintend its culinary affairs, etc. In merchant ships he provides for the tables of passengers, crew, and officers, has charge of the saloons, baggage, etc. In men-of-war there are several stewards. The *paymaster's steward* is now styled in the navy the *paymaster's yeoman*, and he has charge of the store-rooms, issues small stores, serves out rations, and assists in issuing clothing, etc. The *admiral's steward*,

captain's steward, wardroom steward, steerage steward, and warrant-officers' steward, are petty officers, receiving from $19.50 to $41.50 per month, and charged with providing for the various messes under their charge. *Hospital steward*, the former title of the apothecary, which see.

Stewardess. A woman employed in passenger vessels to attend to the wants of female passengers.

Stewart, Charles, Rear-Admiral U.S.N., was born in Philadelphia, July 28, 1778. He entered the merchant service at the age of 13, and rose to the command of an East Indiaman. Was commissioned lieutenant in the navy, March 9, 1798. Was fourth lieutenant of the "United States," under Barry, in the West Indies. In 1800, commanded the schooner "Experiment"; captured the schooner "Deux Amis." Chased by two French vessels, soon after, he captured one, the "Diane," by a skillful ruse, and next a privateer, the "Laura Bridger." Was in charge of the "Chesapeake," in 1801, and in 1802 sailed for the Mediterranean as first lieutenant of the "Constellation," Capt. Murray, and was in the first brush with Tripolitan boats. Returning in 1803, was given command of the brig "Siren," and arrived off Tripoli, October 1, 1803. Convoyed the party, in the ketch "Intrepid," that destroyed the "Philadelphia," and was senior officer of that expedition. Named senior master-commandant in May, 1804, and on the 2d of March captured the privateer "Transfer." Engaged with batteries and boats, in April; in the attacks of August 4, August 7, August 28, and September 3, on Tripoli. Was promoted to captain April 22, 1806. Superintended construction of gunboats in New York, 1806–7, and was in the merchant service from 1808 to 1812; fitting out the "Argus" and the "Hornet," 1812, and then commanded the "Constellation." In conveying her down Chesapeake Bay, he encountered a British fleet, and only avoided it by superior seamanship. Afterward, assisted in the defense of Norfolk. Commanded the "Constitution" next, joining her in December, 1813, and in November, 1814, captured the "Pictou" (14) and other vessels. Sailing again, December 17, crossed the Atlantic, and made two prizes. On the 20th of February, 1815, after a gallant fight, he captured the "Cyane" (20) and "Levant" (18). Was chased by a squadron, and lost the "Levant." He received a gold medal and a sword, the thanks of Congress and of the Pennsylvania Legislature, and the freedom of the city of New York. In 1816, commanded the Mediterranean Squadron in the "Franklin" (74), until January, 1820. In 1821, commanded Pacific Squadron until 1824. For alleged irregularities he was tried on his return home, in 1825, but acquitted. Waiting orders, 1826, 1827, 1828; president Examining Board, 1829; Commissioner of the Navy, 1830–32; waiting orders, 1833–37; Philadelphia Navy-Yard, 1838–41. During the latter year he was spoken of as candidate for President, but not nominated; 1842–43, in command of the Home Squadron; 1844–45, waiting orders; 1846, commanded navy-yard, Philadelphia; waiting orders, 1850–54. In 1852 he became the senior officer of the navy; 1854, navy-yard, Philadelphia, which position he held until 1861; was retired as senior commodore in 1856, when 78, and was promoted to the rank of flag-officer in 1860; was on waiting orders until his death. Promoted to rear-admiral, July 16, 1862. He died at Bordentown, N. J., November 6, 1869, aged 91, having been the senior officer in the navy for 17 years (the eighth to hold that office), and in the service 71 years.—*F. S. Bassett, Lieutenant U.S.N.*

Stick. A term applied to a mast.

Stickle-back. A small fish of the genus *Gasterosteus*, so called from the spines which arm their back, ventral fins, and other parts.

Stiff. That quality in a vessel which enables her to carry a press of sail without careening much. A stiff ship is not necessarily stable. *Stiff bottom*, a hard, tenacious, muddy bottom. *Stiff breeze*, a strong breeze, in which a press of sail may be carried.

STIFFENING-ORDER (*Eng.*). A custom-house warrant, allowing a ship to commence taking cargo before the old is entirely out, to prevent becoming too light.

STIFF-HOOK BLOCK. A block with a rigid hook.

Stiles. The up-and-down pieces in a section of a bulk-head, or those that form the two sides of it. The rails lie across and are tenoned into the stiles. When the panels would be too large, or out of proportion, to fill in wholly between the stiles, pieces called munnions are placed between them in the same direction, and tenoned into the rails.

Still Water. Water not agitated by currents or tides. Slack-tide.

Sting-bull. A fish of the genus *Trachinus* (*T. draco*), which is capable of inflicting severe wounds with the spinous rays of its dorsal fins.

Sting-ray. The *Trygon pastinaca*, a fish with a saw-like bone on the upper side of the tail, which wounds, but does not poison.

Stink-balls. Balls carrying an offensive preparation of pitch, rosin, gunpowder, assafœtida, and colophony, formerly thrown on decks at close quarters.

Stink-pots. Earthen jars charged with a similar mixture to that in stink-balls, and also with hand-grenades, to throw on an enemy's decks.

Stirrup. A short rope, hanging from the yard, with a thimble in the lower end, through which the foot-rope is rove; they are lashed to the iron jack-stay on the yard. An iron plate joining the keel and stern-post, and bolted through them; called also *stirrup-plate.*

Stirrup-plate. See STIRRUP.

Stoach-way (*Eng.*). A small stream of water running through the sand or mud at low-tide.

Stoak. To choke up the timbers so that the pump will not empty the bilge.

Stock. A cross-beam of wood or iron at right angles to the shank of an anchor. The wooden part of a musket, carbine, or pistol. In block-making, a wooden tool having a bit at one end, and a pin with a flat head at the other end. *To stock to*, to pull the anchor stock in an upright position on the bows, by the stock-tackle.

STOCK-AND-BILL TACKLE, or STOCK-TACKLE. A tackle used across the forecastle for the purpose of stowing the anchor, or getting the stock upright, and the flukes on the *bill-board.*

Stock-fish. Cod dried in the sun without salt.

Stockholm, the capital of Sweden, is beauti-

fully situated between Lake Maelar and the Baltic. It stands partly on the north and south sides of the strait, between the lake and the sea, and partly on several islands. A strong citadel has been erected on the small island of Kastellholm, while the fortifications of Waxholm have been so strengthened as to command the only channel by which a hostile approach by sea could be attempted. Among the educational establishments are a technological institute, medical college, and a school of navigation. The harbor, though somewhat difficult of access, is capacious, and has depth of water sufficient for the largest vessels at its quays. It has a considerable foreign, inland, and coastwise trade. Lat. 59° 20′ 36″ N.; lon. 18° 3′ 45″ E. Pop. 166,000.

Stocks. A place properly arranged on the shore of a river or bay, upon which a vessel is to be built. It consists of a number of wooden blocks ranged parallel to each other at convenient distances, with a gradual decline toward the water.

Stockton, Robert Field, Commodore U.S.N. Born at Princeton, N. J., 1796; died there October 7, 1866. A.M. of New Jersey College, 1820. He left New Jersey College in his 15th year; entered the navy as midshipman, September 1, 1811; received honorable notice for gallantry in several battles; was made lieutenant, December 9, 1814; commander, May 27, 1830; captain, December 8, 1838; resigned, May 28, 1850. In 1815, while first lieutenant of the "Spitfire," he distinguished himself by boarding with a boat's crew an Algerine war-vessel. Ordered in 1821 to the coast of Africa, he obtained by treaty from the native chiefs the tract constituting the present republic of Liberia. He also captured many slavers, and a Portuguese privateer of 22 guns. On his return he was successful in breaking up the nests of many West India pirates. In 1826–38, he took an active part in politics in favor of Gen. Jackson, and also in aiding internal improvements in his State. In 1838, he was flag-officer of the "Ohio" in the Mediterranean. He was one of the first to advocate a steam navy; and the "Princeton," built according to his plans in 1842, furnished the model for numerous other vessels. By the explosion of one of her large guns, February 28, 1844, Commodore Stockton was seriously injured. Sent to the Pacific in October, 1845; he with 1500 men, including 600 sailors, in about 6 months conquered the whole of California, and established the authority of the United States there. Forming a provisional government, he returned to the East in June, 1847. The difficulty between him and Gen. Kearney in relation to the supreme command there was subsequently made the subject of a court-martial. U. S. Senator in 1851–53, he strenuously opposed intervention in favor of Hungary, and procured the passage of a law for the abolition of flogging in the navy.

Stoer-mackerel (*Eng.*). The young tunny-fish.

Stoke. To tend the furnace-fires, or the galley-fire. To frequent the galley; to loaf about it.

STOKE-HOLE. The space in front of a steam-boiler from which the fires are managed. See FIRE-ROOM.

STOKER. A fireman in a steam-vessel. One who attends the fires in a furnace. See FIREMAN.

Stonacre (*Eng.*). A sloop-rigged boat for carrying stone.

Stool. A channel abaft the main channel for backstays. A chock under the lower stem-transom, to which the lower ends of the fashion-pieces are fastened. The ornamental block which was formerly placed over the stem for a poop-lantern.

Stop. A small projection at the head of a lower-mast, supporting the *trestle-trees.* A small line used to tie up anything. *Clothes-stops*, small laniards fastened to clothing, to hang it by when washed. *Hammock-stops*, laniards on hammocks for the same purpose. *Awning-stops*, short rope-ends spliced into the ridge of an awning, to serve to tie it when furled. *Awning side-stops*, small lines to haul the edge of an awning out to the ridge-rope. *To stop*, to lash anything temporarily with a piece of small-stuff. To close, as to stop a leak.

STOP HER! An order to stop the engines.

STOP-VALVE. A tight-closing valve attached to a steam-boiler or engine for the purpose of isolating one boiler from steam communication with others, or for thoroughly excluding steam from the engine.

STOP-WATER. An object towed overboard, checking the ship's way. A treenail.

Stopper. A short piece of rope, secured to a bolt, or to any point near a running rope, and used to check the motion of the latter by its friction when wound about it. The ends of stoppers are usually unlaid, and plaited up, so as to make them soft and pliable.

Ropes, or more frequently chains, fastening the anchor in place on the bow.

A rope, chain, or mechanical contrivance serving to arrest the motion of a cable, or to prevent its running out when at anchor. These are of various kinds. *Deck-stoppers*, *laniard-stoppers*, or *rope-stoppers*, are short pieces of rope, having a large knot in one end, and a rope laniard, of smaller dimensions, and in the other end a large hook or shackle for hooking it into a bolt in the deck. The laniard is wound about the cable and stopper, and the knot keeps it from slipping. *Dog-stoppers* are strong ropes fastened to the mainmast, hatch, bitts, etc., to assist the deck-stoppers. When at the bitts, they are *bitt-stoppers;* when in the hatches, *hatch-stoppers;* and when secured to the knees in the wings of large vessels, *wing-stoppers.* *Ring-stoppers* are pieces of rope unlaid and plaited, whose bight is fastened about a ring in the deck, while the ends are wound about the cable. Iron stoppers are used, as *hatch-stoppers* in the corners of the hatches, and *compressors* on the berth-deck, at the bottom of the chain-pipes. Both these are curved iron levers, worked by a tackle, which compress the chain-cable and stop it. A *slip-stopper* consists of two or three short links of chain, shackled or bolted to an eye-bolt or ring-bolt in the deck, with a slip-shackle at the other end. *Check-stoppers* are pieces of rope fastened to a chain, which part by the strain, but check the cable in so doing. *Mechanical*, or *patent stoppers*, are contrivances for arresting the motion of the cable. Many have been devised, but the more common one, *Mix's stopper*, serves as a type of them all. It is an iron casting in a wooden frame, in two parts. The upper part is worked by a screw from above. By screwing it down on the lower part,

but one link is held in the casting, and the next link is stopped. A *lever stopper* is on the same principle, a casting holding but one link, but only while the chain is quiescent, there being no upper piece to hold it in place.

An assemblage of ropes and dead-eyes, used to secure rigging when it has parted. (See FIGHTING STOPPERS.) *To stopper*, to arrest the motion of a running rope, cable, etc., with a stopper.

STOPPER-BOLTS. Large ring-bolts driven through the deck and beam.

STOPPER-KNOT. A knot in the end of a deck-stopper, made by double-walling the end of the rope.

STOPPER-LANIARD. The rope fastened to the head of a stopper. The rope uniting the dead-eyes in a fighting stopper.

STOPPING-UP-PIECES. The middle pieces supporting a ship on the cradle in launching.

Stores. Supplies of any kind.

STORE, or STORE-HOUSE. A house in a navy-yard where any property is stored.

STORE-KEEPER (*Eng.*). An officer in a dock-yard, in charge of all stores and all store-houses. A person superintending a store-house in a navy-yard.

STORE-ROOM. A room in the hold, or on the lower or orlop-deck of a ship, in which stores are placed. *General store-room*, a room in the fore-peak, containing spare articles, iron castings, blocks, rope, duplicate tools, etc. It is under the charge of the yeoman.

STORE-SHIP. A government vessel used for carrying stores, or for storing them away in foreign ports.

Storm. A violent disturbance of the atmosphere, producing wind, rain, snow, hail, sleet, etc. *Wind-storms* are direct, as hurricanes, tempests, etc., or *revolving*, by far the greater number belonging to the latter class. *To storm*, to assault a fortified place by open force.

Storm, Revolving (Hurricane, Typhoon, Cyclone, etc.). *Definition.*—A disturbed condition of the atmosphere extending over a circular area varying in diameter (according to the locality where it occurs) from 50 to 1000 miles, within the limits of which currents of air move with the extraordinary velocity of from 80 to 130 miles an hour around a central calm-space of low atmospheric pressure; while at the same time the whole storm-area moves forward on a track, either straight or curved, at the rate of from 1 to 43 miles an hour.

History of Storms.—The history of this phenomenon (which for the sake of brevity I will call cyclone) dates back nearly 200 years, and the first authentic information on the subject was published in England ("Philosophical Transactions," October, 1698), in a paper on the West India hurricanes, by Capt. Langford, in which paper he speaks of a storm as a whirlwind; describes the veering of the wind within the storm area, and refers to a progressive movement of the storm itself.

The Spanish navigator, Don Juan d'Ulloa, during a cruise on the Pacific coast of South America in the year 1743, experienced several storms in which the wind changed from north to west* (which would occur in the northeast quadrant of a cyclone in the southern hemisphere traveling southward and eastward).

In 1801, Col. James Capper published a work entitled "Observations on the Winds and Monsoons," in which he speaks of great whirlwinds on the Coromandel coast, the centres of which pass generally near Madras or Pulicat, and whose diameter, he says, cannot exceed 120 miles.

A French writer named Romme, in a work entitled "Tableaux des vents, des marées et des courans," published in 1806, describes storms in the China Sea near the Gulf of Tonkin, which he distinctly calls whirlwinds, and applies the same name to other storms experienced in the Mozambique Channel, and again others in the Gulf of Mexico.

Professor Farrar, of the Cambridge University, Mass., in describing a storm that passed over Boston on September 23, 1815 (the account of which was published in the "American Philosophical Transactions," 1819), says that he could not determine the place of the centre or the limits of this storm, but noticed the veering of the wind, and the fact that it veered in opposite directions at Boston and New York at the same time.

In the year 1831, Mr. William Redfield, an American philosopher, published in the *American Journal of Science* a paper, in which he demonstrated not only that the storms on the American coast were whirlwinds, but also that they had a progressive or forward movement, traveling on curved tracks at a considerable rate, and were traceable from the West Indies, along the coast of the United States, curving off to the eastward at some point between the Bermudas and the banks of Newfoundland.

While Mr. Redfield was employed collecting the data from which he eventually deduced his law of storms, a similar investigation was going on in Germany. A number of gales had attracted the attention of German meteorologists, chiefly on account of the oscillations and great fall of the barometer before and during these gales. On Christmas-eve, 1821, the barometer sank so low that many people believed their barometers were out of order, and others, who were not mistaken as to the cause, expected a great catastrophe.

Professor Brandes, a German meteorologist, who had kept a record of observations for a length of time, obtained the registers kept at various places during the same time, and eventually advanced a theory that the winds, during these great storms, blew from all points of the compass in straight lines toward a central space where the barometer was for the time at its lowest stand. (See Fig. 1.)

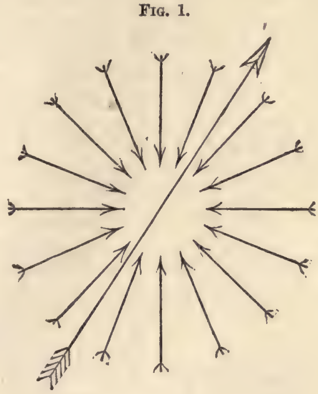
The theory of Mr. Brandes was disputed by Professor Dove, of Berlin, who subjected the observations to a new examination, and made it appear that an explanation of all the phenomena was afforded by the assumption of one or more circular currents or whirlwinds of great diameters, advancing from southwest to northeast. A full account of this is found on page 162, "Dove's Law of Storms," 2d edition, 1862. (See Fig. 2.)

Professor Dove's theory, although under discussion about the same time that Mr. Redfield by an independent course of investigation arrived at the results above mentioned, was not known

* Piddington, p. 82, and "Dove's Law of Storms," p. 108.

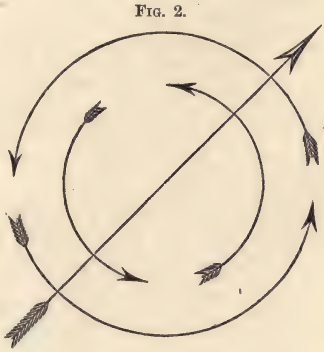
in the United States when the latter gentleman published his paper in the *American Journal of*

Fig. 1.



Science, and an eminent English philosopher, Sir David Brewster, is accredited with saying

Fig. 2.



in connection with Redfield's discovery, "The theory of rotary storms was first suggested by Col. Capper, but we must claim for Mr. Redfield the greater honor of having fully investigated the subject, and apparently established the theory upon an impregnable basis. Mr. Redfield had no knowledge of Col. Capper's discovery when he published his own in 1831."*

In the year 1838, Lieut.-Col. Reid, of the royal engineers, published a valuable work entitled "Reid on the Law of Storms," in which he agreed in all particulars with the views of Redfield, and verified by personal observation all his theory; adding many substantial proofs to the same by investigations of some of the West India hurricanes, and of some in the Southern Indian Ocean.

Col. Reid by his observations of storms in this latter sea further proves Mr. Redfield's theory, that the storms in the southern hemisphere revolve in a contrary direction to those in the northern hemisphere. Col. Reid embodied in his work many useful rules for manœuvring in a revolving storm, and thus may be said to have reduced the science from a mere speculative theory to a practical law; and the recorded experience of hundreds of able and observing men who have carefully and intelligently noted and studied the course and gradual veering of the wind within the limits of the storm-disk goes to prove that correct conclusions have been arrived at in this respect.

Origin of Storms.—With respect to the cause or origin of cyclones we are still comparatively in the dark, but as it is not the purpose of this article to deal with abstract theories or to discuss doubtful scientific questions, I shall confine myself to a brief recital of the opinions of a few gentlemen who appear to have given the subject careful consideration, and spent much time and labor in the prosecution of their investigations.

Mr. Redfield appears to have had no particular theory as to the causes of cyclones; he thought it would be unscientific to attempt to account for them, until better informed, by the exclusive action of any one or more causes. Later, however, he inclines to think them produced by the conflicts of prevailing currents in the different strata of the atmosphere giving rise to circular movements, which increase and dilate to storms.

Col. Reid avoids any general speculation as to the causes of cyclones. He adverts to the possibility of there being some connection between storms and electricity and magnetism, and concludes with an account of an experiment with a 10-inch hollow shot, which, he thinks, partly confirms his views.†

Professor Dove accounts for cyclones by currents of air near the equator being from any cause set in motion toward the poles and coming in contact with other currents moving in a different direction.‡

Mr. Piddington, the author of the "Sailor's Hornbook," in the third edition of that work (1860), pp. 324, 325, gives it as his opinion that cyclones are purely electrical phenomena formed in the higher regions of the atmosphere, and descending in a flattened disk-like shape to the surface of the ocean, where they progress more or less rapidly, according to circumstances. He thinks that whirlwinds, dust-storms, and waterspouts are the same meteor in a concentrated form, but cannot say where the law which regulates the motions of the larger kinds ceases to be an invariable one.

The views of Sir John Herschel on the causes of cyclones, says Mr. Piddington ("Sailor's Hornbook," page 21), may be briefly stated as follows:

"It seems worth inquiry whether hurricanes in tropical climates may not arise from portions of the upper currents prematurely diverted downwards before their relative velocity has been sufficiently reduced by friction on, and gradually mixing with, the lower strata; and so dashing upon the earth with that tremendous velocity which gives them their destructive character and of which hardly any rational account has yet been given. Their course, generally speaking, is in opposition to the regular trade-winds, as it ought to be in conformity with this idea." He then goes on to say that it does not follow that this must always be the case, for, "in general, a rapid transfer, either way in latitude, of any mass of air which local or tempo-

‡ "Dove's Law of Storms," 2d edition, 1862, p. 182.

rary causes might carry above the immediate reach of the friction of the earth's surface, would give a fearful exaggeration to its velocity. Wherever such a mass should strike the earth a hurricane might arise, and should two such masses encounter in mid-air, a tornado of any degree of intensity on record might easily result from their combination."

Sir John Herschel also alludes to the possibility of the meeting of two atmospheric undulations or barometric waves traveling in different directions, producing a storm and giving a rotary motion to the wind.

Professor Espy, an American philosopher, in his fourth meteorological report, 1857, page 11, gives as one of the causes of storms the following: Upon any partial heating of the air at the surface of the earth it rises in columns more or less charged with vapor, which as they rise have their vapor condensed into clouds or rain. Next in this changing of state the vapor communicates its latent caloric to the surrounding air, which also expands, is cooled itself by that expansion, but also gives heat to that part of the air in which it is then, and becoming lighter, is carried farther up. In short, Mr. Espy considers the centre of the storm the base of a huge moving chimney, circular, or of any longitudinal shape, the draft of which is occasioned by an extensive condensation of vapor above.

Dr. Alexander Thom, in a work on storms in the Indian Ocean, south of the equator, gives it as his opinion that circular motion is given to the winds in a storm-area by the contact in meeting on the borders of the monsoons and trade-winds of opposing currents of air, differing in temperature, humidity, specific gravity, and electricity. These, he thinks, give rise to a revolving action which originates the storm.

It is believed by some that cyclones originate at great volcanic centres, and Mr. Henry Piddington is among that number. On page 23, "Sailor's Hornbook," I find the following: "If we produce at both ends the line of the track of the Cuba cyclone of 1844, we shall find that it extends from the great and highly active volcano of Cosseguina, on the Pacific shore of Central America, to Hecla, in Iceland. And in 1821, the breaking out of the great volcano of Eyafjeld Yokul, in Iceland, which had been quiet since 1612, was followed all over Europe by dreadful storms of wind, hail, and rain."

A late writer (Professor Silas Bent), in an article published in the St. Louis *Republican*, November 3, 1878, gives a very interesting solution of the cyclone problem, attributing the motion of the winds within the storm-disk to the earth's rotation on its axis.

For full information on the subject, see the standard works of Redfield, Reed, Dove, and Piddington, already referred to. Also the works of Professors Loomis and Meldrum; "Atmospheric Changes," etc., by Thomas Hopkins; Report of Dr. H. P. Baddeley on "Electric Experiments at Lahore, India, in 1847–50;" Piddington, p. 303; "Etude sur les Ouragans de l'Hemisphére Austral" (2e série), par M. Bridet; "Die Wirbelstürme, Tornados und Wettersäulen," p. 134; and "U. S. Naval Institute Proceedings," vol. v. pp. 236–238.

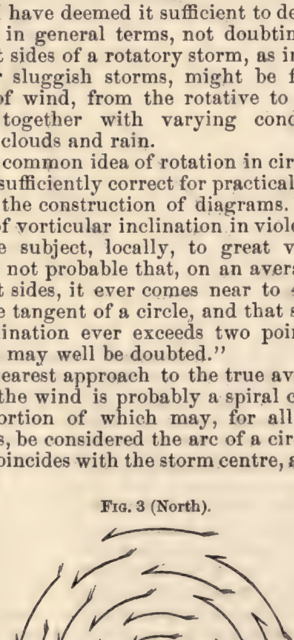
Law of Storms.—The theory of motion of the winds within the storm-area and the progressive movement of the storm, discovered by Redfield and Dove, verified by Col. Reid, and confirmed since its publication by numberless actual observations at sea, is commonly known as The Law of Storms, and is based on the supposition that the air-currents within the limits of the storm-disk move in nearly concentric circles round a centre of low pressure; from right to left, or against the hands of a watch (face up) in the northern hemisphere, and from left to right, or with the hands of a watch, in the southern hemisphere; so that, when facing the wind, the centre lies on the right hand in the northern, and on the left hand in the southern hemisphere.

It must, however, be remembered in this connection that the author of the cyclone theory does not claim that the winds blow uniformly in circles; it is well known that certain irregularities in the course of the winds due to local disturbances frequently take place within the storm-disk, and Mr. Redfield, in the *American Journal of Science and the Arts*, second series, No. 1, page 14, says,* "When, in 1830, I first attempted to establish, by direct evidence, the rotative character of gales or tempests, I had only to encounter the then prevailing idea of a general rectilinear movement in these winds. Hence I have deemed it sufficient to describe the rotation in general terms, not doubting that on different sides of a rotatory storm, as in common rains or sluggish storms, might be found any course of wind, from the rotative to the rectilinear, together with varying conditions as regards clouds and rain.

"The common idea of rotation in circles, however, is sufficiently correct for practical purposes, and for the construction of diagrams. . . . The degree of vorticular inclination in violent storms must be subject, locally, to great variations; but it is not probable that, on an average of the different sides, it ever comes near to 45 degrees from the tangent of a circle, and that such average inclination ever exceeds two points of the compass may well be doubted."

The nearest approach to the true average motion of the wind is probably a spiral curve, any small portion of which may, for all practical purposes, be considered the arc of a circle, whose centre coincides with the storm centre, as in Figs. 3 and 4.

FIG. 3 (North).



The correctness of the circular theory, although generally accepted by seamen who have had

* See also Piddington's "Hornbook," p. 108.

experience at sea and opportunities to observe the changing of the wind, etc., within the actual

Fig. 4 (South).

limits of the storm-disk, is, nevertheless, questioned by several scientific men who appear to have given the subject careful attention.

Thus, Capt. Henry Toynbee, in the report of the British Meteorological Office on the Storms in the North Atlantic, August, 1873, represents the wind on the 25th August as blowing in lines, more or less curved, toward the centre, as shown in Fig. 5. And Mr. Meldrum, from his investigations of the Mauritius hurricane of February 25, 1860, produces a similar figure to represent the movement of the winds in that storm. Fig. 6.

Fig. 5.

Circulation of air, hurricane, August 25, 1873, south of Newfoundland, according to Captain Henry Toynbee.

Fig. 6.

Circulation of air in the Mauritius hurricane, February 25, 1860, according to Mr. Meldrum.

It is stated in the same report (August, 1873), that two days previous, or on the 23d August, the American steamer "Albemarle" hove to north of the centre, and that the captain, finding that he was near the line of the storm-track, subsequently kept the vessel off, and ran with the wind two points on the quarter, N. W. by W., wind E. by S., and thereby cleared the dangerous part of the storm, a fact evidenced by a rise of the mercury and rapid improvement of the weather. A glance at Fig. 5 would make it appear that such a manœuvre was not possible, and it may therefore reasonably be supposed that the diagram does not correctly represent the circulation of air in every storm, and particularly in the one on the 23d of August.

With reference to Mr. Meldrum's diagram of the circulation of air in the Mauritius hurricane of February 25, 1860, we have the report of M. Bridet, *capitaine de frégate*, and captain of the port at St. Denis, that 4 vessels, viz., "l'Angéle," "la Somme," "l'Alfred," and "la Victorine," did cross the track of that storm, and returned to St. Denis and reported the fact.* This feat, according to Mr. Meldrum's diagram, would have been impossible.

The theory of inblowing or centripetal motion of winds (Fig. 1), advanced by Profs. Brandes and Espy, is sufficiently disproved in practice, as may be seen by the foregoing examples of the "Albermarle" and French vessels above referred to, to require no further comments here.

A paper entitled "The September Taifuns, 1878, in the China and Japan Seas," by E. Knipping, published at Tokio (Yedo), Japan, in July, 1879, gives, among other things in its summary of results, the following: "The centre bore 10 points from the wind within a distance of 400 miles from the centre."

"The bearing of the centre varied with the distance, thus: with N. E., N. W., and S. W. winds, the angle† increased with the distance; while with S. E. winds the reverse was the case."

Distortion of the Storm-disk. — Revolving storms, it is believed, are distinct and separate phenomena, created, existing, and dying in accordance with certain natural laws, for which, as yet, no absolute solution has been found; and further, that when unobstructed in mid-ocean, the winds within the limits of the storm-disk circulate, as nearly as may be, in circles around a centre of low pressure; but that from various causes, such as contact with land,‡ meeting or colliding with another storm,§ or temporarily, from local atmospheric disturbances within the storm-disk, the latter may become so distorted as to render it difficult to determine the position of the centre; and to one or more of the above causes, I believe, may be traced most of the defects complained of in the circular system. The fact of but few storms having reached the Mozambique and Formosa Channels is doubtless due to the effect of the high lands of Madagascar and Formosa Islands in turning the storms off to the eastward; and the same effect would be produced by any other high land having a clear expanse of ocean on the side on which the storms approach. Before, however, the course of a storm is changed by pressure against the land which obstructed its original course the storm-disk must necessarily undergo considerable change in form also, and in such cases the barometer and good judgment are all-important.

Remarks on Barometer.—The barometer as an instrument of warning, and also an approximate measure of the distance from the centre of a cyclone, is of vital importance to the seaman.

First. The barometer generally indicates the approach of a storm by a restless, oscillating motion of the mercury, caused by a disturbed condition of the atmosphere in the vicinity of a storm, and the consequent passage over it of atmospheric waves of different heights. These oscillations have been observed to vary from a just perceptible motion to 0.02 inch. One instance is recorded where the oscillations of the barometer amounted to 0.178 inch.‖

† The angle between the direction of wind and bearing of centre.

‡ See "U. S. Naval Institute Proceedings," vol. v. pp. 250–252.

§ See Piddington's "Hornbook," 4th edition, pp. 96–100.

‖ Ibid., p. 239.

Second. The barometer often rises suddenly just on the border in front of a storm, by reason of the air banking up there; and therefore, if the clouds and general appearance of the weather indicate the approach of a storm, the rise in the barometer, if any occurs, is no guarantee that it will not come, but rather a sign that a severe storm is coming. The barometer will probably not rise much in front of a slowly-moving storm.

Third. A very rapid fall of the barometer after fairly entering the storm-disk may be regarded as evidence of a very violent storm of small diameter, and a gradual fall would indicate the contrary.

Fourth. If a vessel by any accident was caught in a cyclone in a dangerous position near the land, the knowledge of her distance from the centre might be all-important, even if it could not be determined nearer than 50 miles, and to aid navigators in determining probably within that distance,—the distance from the centre,—a table is published in Piddington's "Hornbook," 3d edition, page 252, which I give here for what it is worth, and which, in an extreme case, may prove of service:

Average Fall of Barometer per Hour	Distance in Miles from Centre.
From 0.02 inch to 0.06 inch.	From 250 to 150
" 0.06 " 0.08 "	" 150 " 100
" 0.08 " 0.12 "	" 100 " 80
" 0.12 " 0.15 "	" 80 " 50

I have compared the fall of the barometer in a great number of cases with the above, and generally found the result very favorable.

The following table, from Mr. Knipping's publication, "The September Taifuns, 1878, in the China and Japan Seas," shows, according to his observations, approximately the fall of the barometer corresponding to an approach of 50 miles, according to various distances from centre, as follows:

Mean Distance from Centre in Miles.	Fall of Barometer Corresponding to an approach of 50 Miles.
375	0.07 inch.
325	0.08 "
275	0.09 "
225	0.10 "
175	0.12 "
126	0.14 "
75	0.55 "

The figures in the barometer column, divided by 5, give about the corresponding fall per hour.*

The lowest barometer observed at the sea-level is in the case of the "Duke of York," at Kedgeree, in 1833, when the mercury fell to 26.30 inches. In the case of the "Francis Henty" (bark), in a cyclone near the Linchoten group of islands, China Sea, 1872, the mercury fell out of sight, that is, below the wood of which the barometer case was made, the last reading, about one-half hour before reaching the centre, being 27.19 inches. The greatest fall of the barometer in any one storm occurred in the case of the brig "Gazelle," in the China Sea, 1849, when the mercury fell from 29.80 inches to 27.00 inches, or 2.8 inches.

Storm Indications.—The indications of the approach of a cyclone do not differ materially from those of the ordinary gale; but a few such, as a hard steel-gray sky, or having a greenish tint, a blood-red or bright yellow sunset, a heavy swell, unaccounted for in any other way, and a thick, lurid appearance of the sky, may be regarded in connection with a general threatening appearance of the weather, and particularly with a restless state of the barometer, as significant signs of a more than ordinary gale, and, whether seen separately or together, ought not to be disregarded.

When by any of these signs, or by the action of his barometer, the navigator has reason to suspect that a cyclone is not far distant, his first care is to devise a plan for avoiding it, and if he knew positively the direction of its course, this might sometimes be accomplished. An approximate idea of the storm's movement in certain localities may be had by an inspection of a cyclone chart, such as is found in the standard works on storms; but although the cyclone tracks generally lie in the same direction, and as a rule not very far apart,—probably not more than four or five hundred miles at any given point,—yet it does not follow as matter of course that every cyclone travels over the beaten track, and therefore there is no certainty that the approaching storm will do so. By a knowledge of the tracks in the locality the navigator may, however, try to avoid it; but if after doing his very best to effect this he is still caught in the storm, he must then as quickly as possible determine his position in the storm-disk, and the course of the storm. This, on the basis of Redfield's law of storms, may always be done by a knowledge of the following few simple facts committed to memory, viz.:

Rules for avoiding the Centre.—Right Semicircle: Wind changes to the right, N. E. S. W., heave to on *starboard tack.*

Left Semicircle: Wind changes to the left, N. W. S. E., heave to on *port tack.*

This is all that is necessary to place the ship in a safe position north or south of the equator until the course of the storm is determined. This may further be reduced to *six words*, by associating the direction of the change of wind with the semicircle of the storm and the tack to heave to on,—and taking them in this order we would have for the right semicircle: *Right-Right-Starboard*, and for the left semicircle: *Left-Left-Port.*

The right semicircle is that portion of the storm-disk situated on the right of the axis of the storm-track, looking in the direction of its course, and the left semicircle the portion of the storm-disk lying on the left of that line.

Rotation of wind.—Northern Hemisphere: from *Right to Left.* N. W. S. E., left-handed, or, in nautical language, against the sun.

Southern Hemisphere: from *Left to Right.* N. E. S. W., right-handed, or, as a sailor would say, with the sun.

Bearing of centre.—Northern Hemisphere: 8 points (90°) to the *right* of the wind-point, looking in the wind's eye.

Southern Hemisphere: 8 points (90°) to the *left* of the wind-point, looking in the wind's eye.

* It will be observed that this column, when divided by 5, gives, for distances from the centre corresponding to hourly fall of barometer, results differing considerably from those obtained by the use of Piddington's table; and inasmuch as these results place a vessel nearer to the centre than those from Piddington's table, they ought, perhaps, as a measure of prudence, to be preferred.

Two bearings of the centre, with an interval of from 2 to 3 hours between, will in general be sufficient to determine the course of the storm, provided an accurate account has been kept of the ship's way; but if the storm is moving slowly a longer interval may be necessary. There are but two points in the storm-disk of a cyclone where a vessel hove to will not experience a change of wind,—one is in front of the centre on the line of its axis, and the other in rear of the centre on the same line; for these two cases the barometer must be the guide,—in front of the centre it falls, and in rear of the centre it rises.

There are also five points in the storm-disk of a cyclone where a vessel may run along with the storm parallel to its course, and at equal speed, without having any change of wind, and with a steady barometer.

Northern Hemisphere.—1st. *In front of the centre on the line of its axis.* Wind on starboard beam.

2d. *Anywhere in the right forward quadrant.* Wind on starboard side abaft the beam.

3d. *In rear of centre on the line of its axis.* Wind on port beam.

4th. *Anywhere in the right rear quadrant.* Wind on port side abaft the beam.

5th. *Abreast and to the right of the centre.* Wind aft.

Southern Hemisphere.—1st. *In front of centre on the line of its axis.* Wind on port beam.

2d. *Anywhere in the left forward quadrant.* Wind on port side abaft the beam.

3d. *In rear of centre on the line of its axis.* Wind on starboard beam.

4th. *Anywhere in the left rear quadrant.* Wind on starboard side abaft the beam.

5th. *Abreast and to the left of centre.* Wind aft.

The above manœuvres are possible providing sail can be carried, but only three of them are advisable, viz.: the position abreast of the centre, in the rear quadrant, and in rear of the centre. Running along with the storm in front of the centre, or in the forward quadrants, should never be resorted to, as an accident to sails or spars, temporarily disabling the vessel, would at once place her in great danger of being overtaken by the centre.

*To run out of the storm in the Northern Hemisphere.**—Right Semicircle: Haul by the wind *on starboard tack*, and carry sail as long as possible; if obliged to heave to, do so on *starboard tack.*

Left Semicircle: Bring the wind on *starboard quarter.* Note the direction of the ship's head and steer that course. If obliged to heave to, do so on *port tack.*

On the storm-track in front of centre: Square away and *run before it.* Note the course and keep it, and trim the yards when the wind draws on the starboard quarter. If, however, obliged to heave to, do so on *port tack.*

On the storm-track in rear of centre: *Run out* with wind on *starboard quarter*, or heave to on *starboard tack.*

To run out of the storm—Southern Hemisphere.†—Right Semicircle: Bring wind on *port quarter.* Note the course and keep it. If obliged to heave to, do so on *starboard tack.*

Left Semicircle: Haul by the wind on *port tack.* Carry sail as long as possible, and if obliged to heave to, do so on *port tack.*

On the storm-track in front of centre: *Run before it.* Note the course and keep it, and trim the yards as the wind gradually hauls on the port quarter. If obliged to heave to, do so on *starboard tack.*

On the storm-track in rear of centre: *Run out* with the wind on port quarter, or heave to on *port tack.*

A rise of the barometer, improvement of the weather, and a gradual abatement of the force of the wind will result from the above manœuvres; and the ship should in each case be kept on her course until by these signs it is made evident that she is out of danger.

All the above manœuvres depend of course on sea-room, and the ability to carry sail. If sail cannot be carried, or land interferes, the ship must be hove to on the *starboard* tack in the *Right* semicircle, and on the *port* tack in *Left* semicircle, and never otherwise. The old popular idea of heaving to on the starboard tack in the northern hemisphere, and on the port tack in the southern hemisphere, under all circumstances, is dangerous practice and may lead to serious consequences.

It sometimes occurs, although the cases are very rare, that a cyclone takes a sudden turn, and recurves on its track so much as to render a vessel liable to run into it a second time. See "Reid on the Law of Storms," p. 173.

The results of the manœuvres herein recommended should, as before stated, be a rising barometer and improvement in the weather. If, however, the barometer continues to fall, or remains stationary, and the weather becomes either worse or remains the same, it is evidence that the indraft is very great, and in either case the ship should be hauled up as near the wind as possible under the circumstances of wind and sea, and so kept until a decided rise of the mercury and improvement in the weather take place.

Thus the barometer is always a measure of safety, even when the rules laid down for avoiding the centre fail to carry a vessel out of the dangerous part of the storm.

In a very extreme case of indraft, where it is found impracticable to distance the centre by sailing, the vessel should be prepared for a *heavy blow*, and hove to on the proper tack, until either the centre has passed or an opportunity occurs (by a change in the wind) for avoiding it.

Storm-Tracks.—For a correct idea of the tracks generally followed by revolving storms in different parts of the world, reference should be had to the track charts published by Henry Piddington, accompanying the "Sailor's Hornbook."

Velocity or Rate of Travel.—The rate or velocity of translation of revolving storms over their tracks varies not only in different localities, but in storms passing over the same locality, and even in one and the same storm during different stages of its existence. It is generally believed that storms when they originate are nearly stationary, and that after being fully formed they acquire a forward or progressive

movement, which increases more or less rapidly according to the locality in which they blow.

The idea of a uniform increase in the forward or progressive movement of storms cannot, however, be sustained by evidence. Experience, to the contrary, shows that the velocities of translation of particular storms have varied irregularly, increasing and decreasing at different portions of their tracks.

The following table of mean, lowest, and highest velocities, compiled from Piddington's "Sailor's Hornbook," may, however, as far as it goes, serve as a guide to the navigator, who, for practical purposes, desires to ascertain the probable rate of movement of a coming storm:

Locality.	Velocity in Miles per hour.			Remarks.
	Mean.	Lowest.	Highest.	
Atlantic (North)	25.	9.5	43.	This high rate refers to the Cuba hurricane of 1844.
Arabian Sea......	10.	4.0	16.	
Bay of Bengal....	9.	3.0	39.	This high rate occurred only in one instance. From 3 to 15 miles per hour may be taken as the usual rates.
China Seas........	15.	7.0	24.	
Indian Ocean (South).........	5.	0.5	10.	Col. Reid assigns to a cyclone which occurred in 1809 near the Mauritius a velocity varying from 7 to 12½ miles per day.

There does not appear to be at hand sufficient data for the determination of rates for other parts of the world.

Dimensions.—The storms in the Atlantic (North) are said to commence with a diameter of from 100 to 150 miles, and then to increase to 600 or 1000 miles; a fair average is, perhaps, 500 miles. In the Arabian Sea they probably do not exceed 240 miles. In the Bay of Bengal they are from 300 to 350 miles in diameter. In the South Indian Ocean from 150 to 600 miles, and in the China Seas from 80 to 350, and possibly as high as 600 miles.*

Storm Seasons.—The period of the year during which cyclones are most frequent may in a general way be considered. In north latitude, from June to November; August and September being the worst months. In south latitude, from September to May; February and March being the worst months. In other words, the cyclone season appears to correspond to the time when the sun is nearing the equator, on his return from his highest declination in either hemisphere.—*Thomas Nelson, Lieutenant-Commander U.S.N.*

STORM-BREEDER. Heavy cumulo-stratus clouds; also, dark, threatening, cumulo-nimbus clouds. A *weather-breeder.*

STORM-DRUM. A canvas cylinder hoisted in English ports on the approach of a storm.

STORM-FINCH. The *Mother Carey's chicken.*

* See "U. S. Naval Institute Proceedings," vol. v. p. 242.

STORM-FLAG. A flag, red with a white square in the centre, hoisted in American ports on the probability of a storm.

STORM-JIB. The inner jib of square-rigged ships. A strong jib, bent in bad weather. A fifth size of jib, used in cutters.

STORM-KITE. A kite for sending a hawser to a stranded vessel.

STORM-MIZZEN. A triangular storm-sail of stout canvas, bent to the spanker-mast, and used in lying to.

STORM-SAIL. A sail of heavy canvas, bent and set during a storm when lying to. The storm-sails are the *fore-storm-stay-sail*, the *main-storm-stay-sail*, the *mizzen-storm-stay-sail*, and the *storm-mizzen.* The main-trysail and the main-topsail are also used as storm-sails, and also the foresail.

STORM-SIGNAL. A signal hoisted on shore to warn mariners of an approaching storm.

STORM-STAY. A stay for a storm-sail.

STORM-WARNING. See FORECAST.

STORM-WAVES. The waves that precede or follow a storm.

STORMY-PETREL, or STORM-PETREL. The *Mother Carey's chicken*, a small bird of the genus *Procellaria.* See PETREL.

Stove. *Boat stoves* are small stoves for use in boat expeditions, neatly packed in a box. *Hanging stoves*, or *drying stoves*, are small charcoal stoves used for drying decks. *Stove in*, broken in,—applied particularly to a fracture of the casing of a ship caused by collision, grounding, etc. If, on grounding, the bottom is fractured, the ship is said to be *bilged.*

Stow. To put in place or position. *To stow the hold*, to arrange the stores or cargo properly in the hold. *To stow a sail*, to furl or pack it neatly on the yard or in the netting. Stay-sails are *stowed*, other sails *furled. To stow the anchor*, to get it up in place. *To stow the cargo*, to get it on board and properly dispose of it. *To stow the hammocks*, to place them in the nettings. *To stow in bulk*, to stow goods without any packages, as grain, etc. *To stow in bale*, to stow goods in packages.

STOWAGE. The art of properly arranging and disposing the weights in a ship's hold, so that the qualities of the ship shall be the best possible. Reference must be had to stability, speed, easiness of motion, economy of space, and convenience of access. The trim must be accurately preserved, and great weights kept as near the centre as possible.

STOWING-STRAKE. A stealer.

Straggler. See DESERTER.

STRAGGLING-MONEY (*Eng.*). A reward paid for the apprehension of stragglers.

Straight of Breadth. The space before and abaft the midship frame of a ship which does not taper, or is all of the same breadth.

Strain-bands. Bands of canvas across a sail, to take a part of the strain.

Strait. A narrow passage between two bodies of water. See SOUND.

STRAIT-GULF. A gulf with a narrow entrance.

Strake. One breadth of plank, worked from one end of the ship to the other.

Strakes of plank have various names according to their position. The *wales* are those strakes which are worked from the water-line or there-

abouts to the plank-sheer, or lower port-sill. The *bottom-planking* is the name for the strakes from the lower edge of the wales to the garboard-strake. The *garboard-strake* is the name of the strake which comes next to the keel on the outside. The *ceiling* is the name of the strakes worked below the lower deck-clamps. The *bilge-strakes* and *thick strakes* are the strakes worked at the bilge, and are made heavy to support the ship, in taking ground. The *limber-strakes* are those next the keelson. The lower deck *clamps* are the strakes worked from the lower edge of the lower deck-beams to the lower ends of the hanging-knees. The *spirketing* is the two strakes above the water-ways. The upper deck-clamps and ceiling occupy the space between the spirketing and the bottom of the upper deck-beams. *Stringers* fill the space from the port-sill to the plank-sheer. *Thick-strakes* are worked on the deck-beams next the water-ways, and are bolted to the water-ways as well as to the beams. *Strakes of the deck* are the deck-planking, all over the ship.

Strand. A number of rope-yarns twisted together. One of the primary assemblages of wire in a wire-rope. The sea-beach; the shore. *To strand*, to break one of the strands of a rope. To run a ship ashore, on the beach. To drift or be driven ashore.

Strange Sail. A vessel sighted whose nationality, character, etc., are not known

Strap. A shoulder-strap. A band of iron used to connect or hold parts together. A ring of rope, or a binding of iron, put on a block. A piece of rope, spliced to form a ring, used to sling heavy weights, etc., or serving to attach a tackle to any object, etc. A circular, or curved iron band, used for various purposes about a steam-engine.

STRAP-HEAD. A journal-box at the end of a connecting-rod.

Stratus. See CLOUD.

Stray-line. The portion of the log-line which is veered from the reel to allow the chip to get clear of the eddies under the stern, before the glass is turned.

Stray-mark. The mark noting the extent of stray-line.

Streak. A *strake.*

Stream. Flowing water, as a *tide-stream*, the *stream of a current*, etc. *To stream the buoy*, to cast the buoy, attached to the anchor, overboard, previous to letting go the anchor. See GULF STREAM.

STREAM-ANCHOR. An anchor, from one-fourth to one-third the size of the bowers, stowed in the hold or on deck, and used for warping, clubbing, etc. See ANCHOR.

STREAM-CABLE. A cable used with the stream-anchor. In the navy, chain stream-cables are about two-thirds as long as bower-cables, and the links are one-half the diameter of those of the latter.

STREAM-ICE. Drift- or bay-ice, forming and flowing in a current.

STREAM-LAKE (*Eng.*). A lake emptying into the sea by a river.

Streamer. A long and narrow flag, terminating in a point.

Stress of Weather. Continued and sustained violence of the elements.

Stretch. The distance sailed on one tack. To sail by the wind under press of canvas. *To stretch out*, to extend the stroke, and increase the muscular force in rowing.

Stretcher. A sheer-pole. A narrow foot-piece in a boat for an oarsman. A cross-piece put in the slings of a boat, to prevent crushing the sides. A stick placed between the clews of a hammock, to extend them. Jocularly, a lie; a tough yarn.

Stribling, Cornelius K., Rear-Admiral U.S.N. Born in South Carolina. Appointed midshipman from same State, June 18, 1812; served on board the "Macedonian" from January 1, 1813, to April, 1814, and "Mohawk," on Lake Ontario, until April, 1815, and in "Macedonian," in the squadron under the command of Commodore Decatur, when the Algerine frigate and brig were captured, in 1815; from "Macedonian" to "Constellation" in October, 1815, and returned to the United States in "Constellation," end of 1817.

Commissioned as lieutenant, April 1, 1818; on board the "Constellation," on coast of South America, 1819–20; in the West Indies, on board the "Hornet," "Peacock," "John Adams," and "Constellation," 1822–25; in April, 1823, commanded two barges on the coast of Cuba, and after a running fight, captured the piratical schooner "Pilot"; on board the "Brandywine," Pacific Squadron, 1826–27, and sloop "Vincennes," 1827–31; receiving-ship "Norfolk," 1831–33; assistant inspector of ordnance, 1833–35; sloop-of-war "Peacock," East India and Pacific Squadrons, 1835–37; rendezvous, Norfolk, 1840.

Commissioned as commander in 1840; commanding rendezvous, Norfolk, 1840; navy-yard, Washington, 1840–41; commanding sloop-of-war "Cyane," 1841–44; Pacific Squadron, frigate "United States," 1844; receiving-ship "Norfolk," 1845–47; fleet-captain, Pacific Squadron, 1847–48; commanding ship-of-the-line "Ohio," 1848–50; superintendent of the Naval Academy, 1850–53.

Commissioned as captain, August 1, 1853; commanding sloop-of-war "San Jacinto," special service, 1854–55; commandant Pensacola Navy-Yard, 1857–59; commanding East India Squadron, 1859–61; commandant navy-yard, Philadelphia, 1862–64; commanding East Gulf Blockading Squadron, 1864–65; member of Retiring Board of 1855; in 1861, member of a Board of Commissioners (3 Senators, 3 members of the House of Representatives, 1 army, and 1 navy officer), provided for by act of Congress of July 31, 1861, to examine and report as to compensation of all officers of the government, and for other purposes; member of Light-House Board, 1862.

Commissioned as commodore, July 16, 1862.

Commissioned as rear-admiral, July 25, 1866; member of the Light-House Board, 1867–70. Total sea-service, 26 years, 2 months; shore and other duty, 19 years, 1 month. Died, 1880.

Strike. To touch bottom, as a ship strikes on a bar. To haul down the colors, in token of submission. To lower to the deck a topmast, yard, or other upper spar. To send anything below decks.

Stringer. A shelf-piece. In iron ship-building, certain plates riveted fore-and-aft, to strengthen the structure. *Hold-stringers* are plates riveted to the frames in the hold, and connected by

angle-irons to the bottom plating. *Deck-stringers* are strakes of deck-plating riveted on top of the beams next to the side, and joined by angle-irons to the outside plating. Stringers are required by Lloyd's rules in all iron ships.

Strings. The highest strakes in the ceiling of the ship.

Strip. *To strip a mast*, to remove all its rigging. *To strip to a girt-line*, to remove all the rigging from a ship. A whip or girt-line remains at the mast-head for convenience in going aloft when the ship is subsequently rigged. The expression is also used, figuratively, to signify the removing from the person of every article of wearing apparel.

Stroke. In the steam-engine, the distance passed over by a piston in moving from one end of the cylinder to the other. The sweep of an oar. A *gig-stroke* is that given in a gig or long-oared single-banked boat. A *cutter-stroke*, that in a short double-banked boat. A *long-stroke*, one of great sweep. A *short-stroke*, one of little extent, and quicker. A *galley-stroke* is that formerly used in the galleys, and still seen in Portuguese and Brazilian waters. In rowing it, the men rise to their feet as they advance the oar, and fall back as they finish the stroke.

STROKE-OAR. The aftermost oar, giving the time to the others.

STROKE-OARSMAN. The man who rows the after oar if single-banked, or the starboard after oar if double-banked. Both men on the after thwart in a double-banked boat are called stroke-oarsmen, but the starboard-man gives the stroke.

STROKE-SIDE. The side of a single-banked boat in which the stroke-oar is placed.

Strong, James H., Rear-Admiral U.S.N. Born in New York. Appointed from New York, February 2, 1829; attached to sloop "Lexington," Brazil Squadron, 1832–33; schooner "Enterprise," Brazil Squadron, 1834; Naval School, New York, 1835; frigate "Constellation," West India Squadron, 1836.

Promoted to passed midshipman, June 4, 1836; razee "Independence," Brazil Squadron, 1839–42.

Commissioned as lieutenant, September, 1841; frigate "Columbus," East India Squadron, 1844–46; receiving-ship, New York, 1851–52; sloop "Levant," Mediterranean Squadron, 1853–55; receiving-ship, New York, 1856; rendezvous, New York, 1857–58; commanding store-ship "Relief," 1859.

Commissioned as commander, April 24, 1861; commanding steamer "Mohawk," South Atlantic Squadron, 1861; commanding steamer "Flag," South Atlantic Squadron, 1862; commanding steam-sloop "Monongahela," Western Gulf Blockading Squadron, 1863–65.

In November, 1863, Commander Strong convoyed a division of the army under Gen. Banks from New Orleans to Brazos Island, at Brazos de Santiago. On November 25, 1863, a body of troops under Major-Gen. Banks captured a battery of 3 heavy guns at Arkansas Pass. Commander Strong, after assisting in the landing of the troops, steamed ahead and opened an effective fire on the battery, which soon hoisted a white flag and was taken possession of by the troops, who had also engaged it. Gen. Banks commended the effective gunnery of the "Monongahela." Commander Strong commanded the "Monongahela" at the battle of Mobile Bay, August 5, 1864. His vessel was the first to engage the rebel ram "Tennessee." He sheered out of the line to run into her, and struck her fair, at the same time giving her a broadside of solid 11-inch shot, which had, apparently, little if any effect upon her. Soon after signal was made to his ship to again run into her; he did so, and was about to try it a third time, when she surrendered to the fleet.

Commissioned as captain, August 5, 1865; inspector at navy-yard, New York, 1866–67; commanding steam-sloop "Canandaigua," European Squadron, 1868–69; attached to navy-yard, New York, 1870.

Commissioned as commodore, March 2, 1870; light-house inspector, 1871–72.

Commissioned as rear-admiral, September, 1873; commanding South Atlantic Station, 1873–75. Retired April 25, 1876.

Strong. *A strong breeze*, a breeze blowing some 20 to 25 miles per hour (No. 6 in the Beaufort scale), in which, close-hauled, only single- or double-reefed topsails, jib, courses, and spanker would be carried. *Strong gale*, a gale reducing a ship to close-reefed topsails and reefed courses,—No. 9 of Beaufort scale, blowing 35 miles per hour.

Strong-back. A samson-post. A lever over the windlass to lift the chain off of it. A light spar lashed to boat-davits, to which the boat is secured at sea.

Strop. See STRAP.

STROP-BOUND BLOCK (*Eng.*). A clew-line block, with a shoulder on it, and bound with a rope strap.

Struse. A long, unwieldy craft, used on inland waters in Russia.

Strut. A stanchion to the lower-deck beams. A stanchion of the hold. A diagonal shore.

Stubb (*Eng.*). The lower end of a rainbow, foretelling squally weather.

Stub-end. The enlarged end of a connecting-rod, containing the blocks that encircle the pin.

Stud. A piece of cast iron put across the links of large chain-cables to strengthen them.

STUD-LINKS. Links of chain that have studs in them.

Studding-sail. A sail set outside the square-sails in good weather, and when the wind is fair. The word is generally supposed to have been originally *steering-sail*, but a better derivation would seem to be from its former name of *scudding-sail*. These sails are made of light canvas, and roped with light rope. There are on each side, a lower studding-sail, a fore-topmast studding-sail, fore- and main-topgallant studding-sails, and sometimes a main-topmast studding-sail. Royal studding sails were formerly used. The use of studding-sails on board steamers is becoming obsolete. The topmast studding-sail is set with the wind a point free, but the others not until the wind is abaft the beam. They are set on both sides when the wind is exactly aft. In setting a studding-sail, it is first rolled up and then bound by thrusting a toggle in the eyes of a strap, to the end of which a laniard is made fast. When the sail is nearly up, the squilgee is pulled out, and the sail unfolds, and is then set by hauling out the tack, pulling up the halliards, and trimming down the sheet. When taken in, the stud-

ding-sails are neatly rolled up on their yards, and the lower and topmast are stowed about decks, while the topgallant studding-sail is kept in the top, extended along the rigging.

STUDDING-SAIL-BOOM. A spar rigged out for the purpose of setting a studding-sail, and taking its name from the sail above it. The lower studding-sail-boom swings out from the side of the ship. The topmast and topgallant studding-sail-booms lie along the lower and topsail-yards when not in use. When the sail is to be set, they are thrust out beyond the yard-arms. Boom-irons confine them to the yard, in-and-out jiggers handle them, and they are supported by guys when necessary. On the outer end is a jewel-block or a fixed block confined by a pin, through which the tack is rove.

STUDDING-SAIL-BOOM BRACE. A rope leading from the end of the topmast studding-sail-boom to the side of the ship abaft, serving as a brace to support the boom.

STUDDING-SAIL-HALLIARDS. Ropes used to hoist the studding-sails. They lead through blocks at the yard-arms, and are bent to the yards of the studding-sails. The *outer halliards* of the lower studding-sail lead through a block on the topmast studding-sail-boom, and a light whip is used to haul up the upper inner corner of the sail, and is then called the *inner halliards.*

STUDDING-SAIL-HALLIARD BEND. A bend used to fasten the studding-sail-halliards to the yard.

STUDDING-SAIL-OUTHAUL. The tack of the lower studding-sail, leading through a block near the end of the swinging-boom, and through a sheave in the ship's side near the gangway.

STUDDING-SAIL-SHEET. A rope fastened to the inner lower corner of a studding-sail, to assist in retaining it in place. The topmast studding-sail has two sheets, one, the *deck-sheet*, being kept on deck, and used in setting and taking in the sail. The other is called the *short sheet*. See SHORT SHEET.

STUDDING-SAIL-TACK. A rope fastened to the outer lower corner of a studding-sail, and reeving through a block on the end of the boom, so as to haul the sail out in place.

STUDDING-SAIL-YARD. The small spar to which a studding-sail is bent. They are flying yards, and are set and taken in with the sail.

Stuff. Square timber of any thickness. A mixture of tallow, turpentine, etc., applied to the masts, yards, or bottom of the ship in former times. Turpentine and resin was used on the lower masts; tallow on the topmasts; for the side, turpentine, oil, and varnish; for the bottom, tallow, sulphur, and resin.

Stuffing-box. A contrivance by which soft packing material, such as hemp, is confined in an annular space about a rod, spindle, valve-stem, etc., entering a cylinder, pump, or other vessel required to be air-tight. The packing is confined by means of a gland and screws.

Stump. *Stump masts*, masts which have been broken off. *Stump topgallant-masts*, short masts without poles.

Stun'sail. A corruption of *studding-sail*, in common use among seamen.

Sturgeon. A large cartilaginous fish of the genus *Acipenser*. The American species is the *A. oxyrhyncus*. From its roe caviare is made, and isinglass from its muscular parts.

Subbrachian. One of an order of malacopterygious fishes, comprising those which have the ventral fins situated either immediately beneath or between, or a little in front of or behind, the pectoral fins.

Sub-calibre. A term applied to projectiles that are smaller than the bore of a gun, and that are enlarged by expanding bands, sabots, etc.

Sub-lieutenant. The rank next below lieutenant in the English navy.

Submarine Bank. A bank with deep water over it.

Submarine Boat. A boat for use below the surface of the water.

Submarine Explorer. A double diving-bell, furnished with air- and light-chambers, and appliances for purifying the air contained within.

Submarine Gun. A gun intended to project a shot below the surface of the water. Submarine weapons are said to have been devised by Calluricus for use with Greek fire, but doubt exists of this. In 1797, Saint Cyr proposed a catamaran with a submarine gun. Fulton, in 1814, experimented with such guns in New York harbor. Mr. Phillips, of Indiana, in 1855, and Mr. Woodbury, of Boston, in 1861, made experiments with these guns, firing them under water, and the latter gentleman has made other plans since that time for using these guns. "Jones's submarine battery" shattered a raft passing over it in New York harbor in 1862. A submarine gun was shown in the Paris Exposition in 1867, designed by a Mr. Duffy. Experiments made in England in 1864 demonstrated that guns could be successfully fired under water, and that the projectile acquired considerable velocity, and deviated considerably. Ericsson in experimenting with submarine guns, for use in his torpedo-boat, at first used steam, but later, had recourse to explosives. His experiments are not concluded. The necessity of a weapon that will attack the ship below the water has given, since the advent of armored vessels, considerable impulse to the subject of submarine guns, but at present they are not so greatly developed as submarine mines or torpedoes.

Submarine Lamp. A lamp for use under water. Many such have been devised, but they will now be replaced by the electric light.

Submarine Mines. The term "submarine mines" is applied to defensive mines, or those which would be used to obstruct the channel of a river, or the approaches to a fortified seaport. Col. Samuel Colt, the inventor of the revolver, first demonstrated the practicability of blowing up vessels by submarine mines fired by electricity. After many years devoted to experiments, about the year 1842 he blew up the old gunboat "Boxer" with a submarine mine, exploded by means of a galvanic battery. After destroying several hulks at anchor, on the 13th of April, 1843, on the Potomac River, he blew up a brig while under way, sailing at the rate of 5 knots an hour. He had stationed himself at Alexandria, 5 miles distant from the mine. Nothing further was done at the time, although Col. Colt, in a letter to the President of the United States, clearly explained the great value of this invention for defending our harbors from an enemy.

The Russians used submarine mines to defend their ports during the Crimean war, but no vessels were destroyed by them.

The South, during the late civil war, first proved the great value of submarine mines for river and harbor defense. The torpedo and submarine mine were never before fully recognized as legitimate engines of war.

The first mines encountered by the Federal navy were planted in the Savannah River, about February, 1862, but for some time they were so crude in construction as to cause little damage. However, during the summer of 1863 they became very effective. One of the most successful of the many kinds employed by them was the Singer torpedo, as it was then called. This consisted of a tin case holding from 50 to 100 pounds of powder arranged so that it was buoyant, and anchored in the channel at the proper depth. It had on its top a heavy cast-iron cap, which, when the torpedo was struck by a passing vessel, fell off, thus pulling a string fastened to a small pin. The pulling out of this pin caused the explosion of the mine. Obstructions in channels and on bars were frequently made much more formidable by submarine mines fitted with fuzes to explode by contact when struck by a vessel's bottom. Regular frames were sometimes constructed to support the mines. These were called "frame torpedoes." The Federal gunboats never tried to force a passage through a channel defended in this manner.

A great number of buoyant mines were used by the rebels, particularly in the beginning of their use of submarine mines. These consisted of barrels or other vessels partially filled with powder, and anchored in channels and harbors; they were fitted with sensitive or contact fuzes, and were much dreaded by our navy.

Towards the end of the war, during the summer of 1864, the rebels planted enormous mines at Charleston, Mobile, Fort Fisher, and in the James River. At first old boilers were used as cases, but soon regular ones were made. These mines were fired by electricity, and proved very effective. During the war 7 monitors and 11 wooden vessels of war were totally destroyed by submarine mines, and all these occurred during the last half of the conflict. Had the rebels possessed the same knowledge of submarine mines and torpedoes at the beginning of the war that they possessed at its end, the struggle would at least have been much prolonged. While submarine mines arranged to explode on contact with a vessel may be useful to a blockading force and other special occasions, the certainty of explosion by electricity makes that the desirable method, when they are intended to assist in the defense of a river or harbor. Besides, when fitted with electrical fuzes they allow friendly vessels to pass over them in safety.

The difficulty originally in using electricity to explode the mines was in determining the exact relative position of the vessel and mine, so as to produce an effective explosion. But by planting the mines in groups, and by careful ranges, together with the use of plane tables and other instruments suitable for the purpose, the position of the vessel can be accurately determined. The firing of the mine the instant the vessel is proven to be over it by two distinct ranges is now done by a self-acting instrument, invented for this purpose. The use of gun-cotton has added to the efficiency of this method of defense, as that explosive is not injuriously affected by dampness. Formerly the great number of insulated wires required—two, and afterwards one to each mine—was a serious trouble in putting down submarine mines, but a recent invention of Capt. McEvoy's, called "McEvoy's single main system," does away with the necessity of more than one wire from the battery on shore to the group of mines. Each mine is connected by a wire of its own to the "junction," and a single wire connects this instrument to a similar one on shore. By means of this invention each mine is under as thorough control as though it had a wire of its own.

The importance of submarine mines for the defense of our harbors and coast cannot be overestimated, yet they should be, in order to be thoroughly efficient, supported by heavy rifled guns, so that the enemy's vessels would be unable to drag for them or destroy them by any means. The manufacture and planting of submarine mines for harbor defense in this country is one of the duties confided to the army. They are exploded from the forts nearest at hand. This is chiefly a matter of nice calculation. Whereas the manufacture and use of torpedoes belongs to the navy. In their successful employment is required the highest order of personal courage, coolness, and determination under the most trying circumstances.—*R. M. G. Brown, Lieutenant U.S.N.*

Submarine Navigation. Navigation of the depths of the ocean by means of submarine boats.

Submarine Projectiles. Projectiles for use below the surface of the water. Shot, shell, and rockets are used, and differ little, if any, from those used above the surface.

Submarine Rocket. A rocket for use under water. Such rockets were used as early as 1730 in France. In 1823, Joshua Blair devised them in America, but they were not put in use. Montgery, in France, proposed a battery of rockets in 1825, firing them from a gun under the surface, using a lap-valve in the ship's side. Major Hunt tried rockets from a 12-inch gun in a caisson in 1862. He was drowned, and experiments ceased. Mr. Quich, in England, in 1872, Mr. Weir, of New York, in 1874, Gunner Burdett, of the U. S. navy, in 1874, and Van Schelila, in Russia, in 1874, have all proposed and planned rockets more or less successful.

Submarine Telegraph. A telegraph wire-cable armed to prevent the action of water, grinding on rocks, etc., crossing the shallower sea-depths. The first was laid in 1858, across the ocean. See TELEGRAPH CABLES.

Submarine Telescope. A telescope used for looking at objects below the surface. It consists of two tubes united, one of which is thrust into the water, the other throwing light into it.

Submarine Thermometer. A thermometer for use in sea-depths, specially constructed to sustain the great pressure of the water. See DEEP-SEA SOUNDING.

Submarine Valve. A valve used in connection with a submarine gun, opening in the side of the ship, and allowing the gun to emerge.

Subsidy. A sum paid to the owners of steamer-lines, to aid them in establishing the line. Subsidized steamers are generally available for war purposes, and some have been built with a view to their use as cruisers.

Subsistence. The amount of rations, clothing, etc., furnished to men.

Suck. To draw air when the water is low, said of a pump. *To suck the monkey* (*Eng.*), to rob the grog-can.

Sucker. The lump-fish. The sucking-fish, or *remora*.

Sucking-fish, or Suck-stone. This fish has a long oval plate on the top of the head, by which, having exhausted the air in it, it clings to a ship's bottom, to the sides of a shark, or to turtle. Among the ancients the remora was credited with power to impede and even arrest the progress of vessels,—the delay of Antony's ship in getting into the battle of Actium being attributed to it. A curious use of the remora, said to prevail on the coasts of Mozambique, is as an auxiliary to the fishermen, who, fixing a ring, with a cord attached, around its tail, place it in a vessel of sea-water and carry it in their boat till they discover a sleeping turtle, when, having approached as near as practicable, they throw the remora in the direction of the turtle, to which it seldom fails to attach itself, when drawing in the cord the fishermen secure their prize.

Suction. A term applied to the tendency of matter, under atmospheric pressure, to fill a vacuum.

Suction-pipe. A pipe through which a fluid is supplied to a pump, either by its weight or the atmospheric pressure.

Suction-valve. The receiving-valve of a pump, or one which prevents the reflux of a fluid through the suction-pipe.

Suez. A frontier seaport town of Egypt, near the head of the Gulf of Suez. It is connected by railway with Cairo and Alexandria, and since the construction of the Suez Canal, which crosses the Isthmus of Suez from Port Said to this town, it has greatly improved. It has always been a place of extensive transit trade. Two miles south of the town is a spacious new artificial port, with a dry-dock, besides which there is a canal-port, with extensive buildings, and a quay. Lat. 29° 58′ 6″ N.; lon. 32° 34′ 2″ E. Pop. 13.000.

Suffren de Saint-Tropez (Pierre André de), commonly known as the Bailli de Suffren, and one of the most illustrious of French seamen, was born at Saint Cannat, near Lambesc, in 1726, and died in Paris in 1788.

Suffren's whole life may be said to have been passed in fighting the English. As was, and is, still customary among noble families, that of Suffren (to increase the fortune of an elder brother) devoted the younger to the Order of Malta and to a sea-life. Fortunately the young aspirant was eminently fitted for, and loved his destined profession. He not only possessed the most dauntless courage, but had acquired a great deal of general knowledge, and was early distinguished for elevation of character and coolness of judgment. In spite of his fitness for the naval service he made his way in it rather slowly, considering his family, and the spirit of the times.

Entering the navy in 1743, he was, after several very active cruises, made ensign in 1748; and with that rank took part in the operations at Belle Isle, where he was made prisoner by the English. The treaty of Aix-la-Chapelle restored him to liberty, and he then went to Malta, where he took active service for a considerable period. In 1754 he re-entered the French Royal Marine, and was employed in the squadron of La Galissonnière at the siege of Mahon, in 1756. Was again made prisoner in 1759, and after various vicissitudes and constant service, finally attained the grade of *capitaine de frégate* in 1767. After attaining this rank in the French navy, he made several cruises in the galleys of his order, and became a Commander of Malta.

The title of *Bailli*, by which he is best known, was not given to him until some years after this time.

Becoming *capitaine de vaisseau* in 1772, he served with great credit in the Levant, and afterwards in the French fleet which served on the American station during our Revolution.

When it became plain that most active measures were necessary to prevent the seizure of the French and Dutch East Indian colonies by the English, Suffren was the officer selected to protect French interests, and to uphold the honor of his flag in those distant seas.

Sailing from Brest, as *chef d'escadron*, or commodore, of a squadron composed of 5 line-of-battle ships and 2 frigates, he carried out a body of troops destined for the Cape of Good Hope. On the passage, in the latitude of the Cape Verde Islands, April 16, 1781, he encountered an English squadron, with which he had a successful fight, and proceeded to the Cape of Good Hope, which colony he reinforced and reprovisioned.

From the cape he sailed for the Isle of France, where he united his squadron with that of the Count d'Orvès.

The death of that officer soon left him in command of the fleet, and in February, 1782, he inflicted a crushing defeat upon the English fleet under Admiral Hughes, near Madras, after which he concluded an alliance with the celebrated Hyder Ali, who was then striving against the English with great desperation.

Suffren again defeated an English fleet off Negapatam, formerly the capital of the Dutch possessions in India, and captured Trincomalee. The English, indeed, never had so capable and worthy an opponent in that part of the world, and were no doubt relieved when the peace of Versailles, in 1783, caused the French seaman to return home, where he was received enthusiastically and loaded with honors.

New complications with England having arisen in 1787, Louis XVI. gave Suffren the command of a fleet fitting out at Brest; but he died suddenly, at Paris, just as his orders were made out.

It was given out at the time that he died of apoplexy; but, according to Jal, the historiographer of the marine, he was killed in a duel. The story was that the Bailli de Suffren had punished two young aspirants, serving under his orders, for some military breach; and when their relative—a grand signeur—came to the Bailli to plead for them, the latter used no measured language in regard to them and their offense.

A duel ensued at once, the Chevalier Bemin being the witness. Suffren was greatly at a disadvantage, as he was so fat as to be unwieldy. His groin was pierced by his antagonist's sword, and he died almost instantly.

The Bailli is described as being not above the ordinary height, but immensely fat. He had very regular features, and a very noble and

pleasant expression. His manners are said to have been polished and easy, while to his inferiors he was particularly kind and considerate.

His men, knowing his courage, coolness, and judgment in action, were willing to follow him anywhere, and Suffren was as quick to notice and reward courage and conduct as he was sure to detect and punish the least ill-conduct or cowardice.—*E. Shippen.*

Sugar-loaf. A hill shaped like a sugar-loaf. Applied to the waves, a sugar-loaf sea is one in which the waves rise into sugar-loaf shapes, with little wind.

Sugg (*Eng.*). To move or roll heavily on a bank or reef.

Suit. *Suit of sails*, a set of sails.

Sullage. The deposit of mud and silt by water.

Sullit. A broad and deep Dutch fishing-boat.

Summary Court-martial. See COURT-MARTIAL.

Summer-blink. A transient sunny spell in bad weather.

Sumner's Method. See NAVIGATION.

Sump. A swamp or bog.

Sun. The direction of the sun in the northern hemisphere is to the right of an observer looking to the north, hence motion to the right, or from left to right, is *with the sun.* Motion in the opposite direction is *against the sun.*

SUN-DOG. A portion of a luminous circle about the sun.

SUN-FISH. A soft-finned fish of the genus *Orthagoriscus* (*O. mola*), having a short disk-like body and two fins. The *Selachus maximus*, or *basking shark.*

SUNRISE AND SUNSET. It is important to the navigator to know the times of sunrise and sunset. A gun is fired at sunset in every harbor where there is a man-of-war, colors are hauled down, etc. The time of sunset is given in nautical tables, and is tabulated for all latitudes and declinations. It is usual to hoist boats, and sometimes light yards are sent down at sunset.

SUN-STAR. A star-fish; the *Solaster papposa.*

Sunderland. A borough and seaport town of England, at the mouth of the Wear, in the North Sea. The town proper occupies a peninsula between the expansion of the Wear and the sea. This is one of the principal ports of England for the shipment of coal; it has besides a large export of lime, glass, earthenwares, rope, and chemical products. Mercantile ship-building is extensively carried on. The harbor is defended by batteries, and connected with it are large docks. Lat. 54° 54′ N. Population of the borough 99,000.

Sunken Rock. One lying beneath the surface.

Sunken Vessels, Raising. Sunken vessels are now raised by various methods. One, very successful, consists in sending down and attaching to the hull a number of casks, containing compressed air in chambers, liberated after the casks are attached. Small vessels are raised by chains and powerful steam appliances for heaving in on them.

Sunn-hemp. Also called brown-hemp, or Madras hemp, a kind of hemp made from the fibres of a kind of Indian plant; the *Crotolaria juncea.*

Superannuated (*Eng.*). Retired from service on account of age.

Supercargo. A person in the merchant service charged with the sale of the cargo, and other commercial transactions.

Superheat. To heat, as steam, after separation from the water, thereby increasing the elastic properties.

SUPERHEATER. A part of or attachment to the boiler, in which the steam is superheated.

Superior. See CONJUNCTION, PLANETS.

Superior Officer. An officer whose rank is higher in comparison with another. A senior officer.

Supernumeraries. Men above the regular complement, borne on a separate list. Extra members of a ship's, boat's, or gun's crew.

Supporter. A curved knee, placed under the cat-head. A pin at the hounds of the mast, to support the trestle-trees in small vessels.

Sura. Another name for *toddy.*

Sures. Southerly winds on the west coast of South America. When rain or fog comes with them, they are *sures pardos.*

Surf. The swell of the sea breaking upon the shore or on rocks, etc. Properly speaking, surf is only those swells breaking in gradually shallowing water on approaching a shore, each of which is a roller; while the sudden breaking up of waves on rocks or other obstacles are *breakers.* In rowing to seaward the danger is that a heavy sea will up-end the boat, or turn it broadside on. If sufficient command can be kept over the boat, the sea is avoided, if possible, so as not to meet it at the moment of its breaking. If impossible to avoid the sea, give the boat sufficient speed to prevent her being carried back by the wave.

In rowing before a heavy surf, the effect of a sea is to throw up the boat's stern and to depress her bow. If she then have sufficient inertia she will assume in succession the descending, the horizontal, and the ascending positions, as the wave passes under her stern, her midships, and her bow. If a boat with little inertia be overtaken by a heavy roller, her stern is raised, and the boat is carried along bodily on the front of the wave, the bow meanwhile immersed in the hollow of the sea, where the water is comparatively stationary and offers a resistance. The danger now is that the boat will be turned end-over-end, or that she will broach to. To lessen the danger attendant upon rowing in before the surf, the following instructions have been laid down:

1. As far as possible avoid each sea by placing the boat so that the sea will break ahead or astern of her.

2. If the sea be very heavy, or if the boat be very small, and especially if she have a square stern, bring her bow around to seaward, and back her in, rowing ahead against each surf that cannot be sufficiently avoided to allow it to pass the boat.

3. If it be considered safe to proceed to the shore bow foremost, back the oars against each sea on its approach, and if there is a drogue, or anything in the boat that may be used as one, tow it astern to aid in keeping the boat end-on to the sea.

4. Bring the principal weights in the boat toward the end that is to seaward, but not to the extreme end.

5. If a boat worked by sails and oars be running under sail for land through a heavy sea, her crew should, unless the beach be quite steep,

take down her masts and sails before entering broken water, and take her to land under oars alone. If she have sails only, her sails should be much reduced, a half-lowered foresail, or other small head-sail being sufficient. A boat should be steered with an oar over the stern.

Landing in a Surf.—On a flat shore the boat is kept end-on to the sea until she is fairly aground, and she is then taken farther in by each sea, aided by the crew, who jump out to lighten her, and drag her in. On a steep beach it is the general practice, in a boat of any size, to retain speed right on to the beach, and in the act of landing to turn her bows half round, so that she may be thrown on her broadside upon the beach. When the surf breaks only a short distance from the beach, a boat may be anchored outside the surf, and veered or backed in from her own anchor.

SURF-BOAT. A boat used to land passengers and freight in a surf. Boats of various forms are used, and the natives of many of the Pacific islands have some very good boats for this purpose.

SURF-DUCK. The *Anas perspicallata.*

Surface-condenser. A condenser in which steam is condensed by contact with cold metallic surfaces. See CONDENSER, MARINE STEAM-ENGINE.

Surface-current. The deep-sea currents of the surface. (See CURRENTS.) Fresh water running over salt at the mouths of rivers.

Surface, Water-heating. The surface in a steam-boiler from which the heat of the fire is absorbed by the water.

Surge. A large swelling wave. The tapered part of the whelps on a capstan. The slacking-up of a cable on the capstan. The swaying motion of a ship that is aground as she rises to the seas. To swell, as the waves. To slacken up a rope suddenly. To rise and fall with the heave of the sea when on a reef. *To surge the capstan*, to slacken the rope about it. *Surge ho!* a warning given when a rope is to be surged.

Surgeons. The name of surgeon does not appear in any of the accounts of the British navy before the year 1557, although probably of much earlier date in that establishment. During the civil wars of Charles I.'s time it was not uncommon for doctors of medicine to act as captains and command regiments of cavalry and infantry.

The title is a contraction of the French *chirurgien*, Latin, *chirurgus*, both derived from a Greek word signifying operating with the hand. In Spanish the word is *cirujano*, Portuguese *cirurgiao*, Italian *chirurgo*.

The medical corps of the royal navy is composed of a director-general, inspector-generals of hospitals and fleets, deputy inspector-generals, staff-surgeons, first and second class, and surgeons.

Old Sir William Monson says, "The surgeon is to be placed in the hold, where he should be in no danger of shot; for there cannot be a greater disheartening of the company than in his miscarrying, whereby they will be deprived of all help for hurt and wounded men." See MEDICAL CORPS.

SURGEON'S DIVISION. The apothecary, nurse, and others attached to the medical department on board ship.

SURGEON'S MATE. A former rank in the English navy, now *assistant surgeon.*

Survey. An inspection or examination into stores, etc. To ascertain the form, dimensions, position, etc., of a portion of the surface of the earth.

SURVEY, BOARD OF. A board of three or more officers, appointed to survey government property to ascertain its condition and disposition. Surveys are ordered by any commanding officer on representation of the necessity therefor, or on all stores purchased or made for the service. Boards may summon experts to assist them. They must ascertain the cause, nature, and extent of the damages, and recommend the disposal of condemned property. All purchased articles must be passed by a board before they are paid for. A *medical survey* is ordered on any persons so disabled as to make it desirable or necessary.

SURVEYING. The art of determining the area, etc., of any part of the earth's surface, and delineating it on paper. See CHART, HYDROGRAPHY.

SURVEYING-VESSEL. A vessel fitted for making a maritime survey.

SURVEYORS. Examiners employed by underwriters. Two officers, formerly on the English Naval Board, charged with the building and repairing of ships in the navy.

Suspend. To debar an officer from the execution of the duties of his office. Unless the officer is to be brought before a court-martial, his suspension cannot exceed 10 days.

Svalocin. The star *a Delphini.*

Swab. A long mop, made by binding rope-yarns in a bundle, used to dry the decks, etc. *Hand-swab*, a small swab made from the threads of canvas. The term *swab* is applied to an epaulet, and also, in an uncomplimentary way, to a sailor.

SWAB-ROPE. A rope bent to a swab, for dipping it overboard.

SWAB-WASHER. The captain of the head.

SWABBER (*Eng.*). Formerly, a petty officer on board a man-of-war, whose duty was to see the decks clean. (*Eng.*) A man formerly appointed to use the swabs in drying decks; called also ship's sweeper, or captain of swabbers.

Swad. A fish-basket.

Swag. To sink down; to sag down.

Swage. A tool used by shipwrights in driving in eye-bolts, etc.; it is made to fit the head of the bolt, so that in driving or striking on the swage, the bolt is forced in without bruising the head of it. It is also used by shipsmiths in making the various kinds of bolts.

Swallow. The aperture in a block through which the rope reeves.

Swallow-fish. The *Trigla hirundo*, a fish with large gill-fins; also called *Sapphirine gurnard.*

Swallow-tail. The points of a *burgee*, or swallow-tailed flag.

Swamp. To capsize or fill a boat with water.

Swape. A wooden support for a light. A pump-handle. A long oar used in English *coal-keels.*

Swart-back. The great black and white gull; the *Larus marinus.*

Swash. A sudden surge of the sea. A shoal in a tideway, over which the tide ripples. A narrow sound inside of a shoal.

SWASHWAY. A channel across a bank or among shoals.

Swathe (*Eng.*). The entire length of a wave.

Sway. To hoist; to raise. *To sway on end*, to hoist to a perpendicular position from the deck. *To sway across*, to sway a yard to a horizontal position. *To sway away on all top-ropes*, figuratively, to go to great lengths.

Sweat-box. A narrow cell in which prisoners were formerly confined.

Sweating the Purser (*Eng.*). Wasting the stores, burning candles up, etc.

Sweden and Norway, Navy of. Although Gustavus Adolphus set little store by a naval power, the exigencies of later wars than that in which he took so conspicuous a part have obliged the combined states (now under one monarchy) to possess considerable fleets. Washed on one side by the Baltic and on the other by the North Seas, Norway and Sweden have always produced hardy seamen and skillful navigators, and whenever engaged with an enemy they have given a good account of their potency. At the present time the navy of Sweden is divided into two branches,—the navy proper and the "coast artillery." The navy consists of 38 vessels, all unarmored, and mounting 325 guns. The largest ship, the "Stockholm," is of 2850 tons displacement, carrying six 7-inch and sixty 30-pounder guns, and has a speed under steam of 6½ knots per hour. The next in rank is the "Vanades," of 2130 tons, armed with 16 guns, and having a maximum speed of 11 knots. There are also 18 unarmored gunboats, 4 corvettes, and 12 sailing-vessels. The coast artillery is the most important arm of defense, its total force being 120 vessels of all kinds. The most important are the 4 monitors, "Loke," "John Ericsson," "Thordoen," and "Tyrfing." The largest of these, the "Loke," is of 1600 tons displacement, 450 horse-power, and has a thickness of armor of 5 inches at the water-line; her armament consists of two 10-inch guns mounted in a single fixed turret. The others are of nearly the same size and power. There are also 10 armored gunboats with fixed turrets, 44 sloop-rigged galleys, 6 mortar-launches, and 53 yawls. The headquarters of the navy is at Stockholm, the island of Skeppskolm being occupied as the repairing and outfitting yard, and there is also a naval establishment at Carlscrona.

The small fleet of the Norwegian navy is composed of 4 monitors, 1 frigate, 4 corvettes, 1 sloop, and 22 gunboats; also 4 sailing-vessels, and 2 torpedo-boats. The monitors are the only armored vessels in the navy. There are, in addition to the above, 83 small boats of different kinds, carrying from 1 to 6 guns each. One of the monitors, the "Thor," is of 600 horse-power and 2003 tons displacement; another, the "Thrudnang," has 500 horse-power and 1575 tons; the third, the "Mjalner," 1515 tons and 450 horse-power; and the fourth, the "Skarpianen," 1447 tons and 350 horse-power; and the armament of each consists of two 9-inch Armstrong guns mounted in a single revolving turret. The "Thor" has 7 inches of armor, the others 5 inches. The frigate, the "Kang Suerre," is of 1500 horse-power, 3472 tons displacement, and mounts 50 guns. Of the corvettes, the "St. Olaf" is of 1100 horse-power, 2182 tons displacement, and carries 38 guns; the "Nordstjernen," 1609 tons, 720 horse-power, and 19 guns; the "Nidaros" and "Nornen" are of 1700 and 1550 tons displacement respectively. The fleet will soon be strengthened by the addition of 3 gunboats building at Stockholm. The navies of these two countries are distinct services, each having its own complete organization and administration. The Norwegian navy is represented in the cabinet by a rear-admiral, chief of the marine department, who is assisted by a second rear-admiral, chief of staff. The central control at Stockholm is divided into three main sections, with controllers at their heads, and subdivided into bureaus. The general administration is divided in control between two dockyards, Christiania and Stockholm. There is also a naval academy, hydrographic office, and observatory. The Swedish navy is represented in the cabinet by a minister of marine, the central control having two main divisions, chancellery and command. There is in addition a commander-in-chief of *personnel*, a military department, construction department, commissariat department, pilotage department, naval school, and hydrographic office. The general administration is divided between the two naval stations of Carlskrona and Stockholm. The *personnel* of both navies is recruited by voluntary enlistment, there being a special arrangement for conscription in case of war in the maritime districts of all persons between the ages of 22 and 35 years. The annual expense of the Norwegian navy is about $600,000, and of the Swedish navy about $1,500,000. The *personnel* consists of 108 commissioned officers and 150 non-commissioned and 2080 enlisted men in the navy of Norway, and the royal fleet of Sweden is manned by 5607 men, distributed as follows: vice-admiral, 1; rear-admirals, 3; commanders, 5; captain-commanders, 20; captains, 43; lieutenants, 43; sub-lieutenants, 26; engineers, 13; medical officers, 24; petty officers of first class, 401; petty officers of the second class, 844; mechanicians and workmen, 150; seamen, 2385; seamen employed on shore, 1310; recruits, 339. Total, 5607. There are no foreign squadrons in either navy, the Norwegian ships are entirely confined to coast defense, and in the Swedish fleet the cruising is confined to single vessels. There is a royal naval reserve besides the force actually in commission, and a Beööring which numbers 40,000 men. All sea-faring men and dwellers in seaports are amenable to the maritime conscription.

Sweep. The trend of a coast to a crescent. A large, broad oar used in racing-boats, and formerly to propel small craft in a calm. The curve of the leech of a sail. To drag with the bight of a rope for an object at the bottom of a harbor. To scan the heavens rapidly, and in a systematic manner, in search of a star. *To sweep down*, to clean the decks with a broom. *Sweep of the tiller*, the arc on which the end of the tiller traverses.

In the year 1800, and for some time afterward, it was customary in forming ship's bodies to design portions of the frames by the use of arcs of circles called sweeps, of which there were generally five:

1st. The *floor-sweep*, which is limited by a line in the body-plan perpendicular to the plane of elevation, a little above the keel, and the height of this line above the keel is called the dead-rising. The upper part of this arch formed the head of the floor-timber. If a straight line be

drawn from the upper edge of the keel to touch the back of the floor-sweep, the form of the midship-frame below the lower height of breadth will be obtained.

2d. The *lower breadth-sweep*, the centre of which was a line representing the lower height of breadth.

3d. The *reconciling sweep* joins the two former without intersecting either, and makes a fair curve from the lower height of breadth to the rising line.

4th. The *upper breadth-sweep*, the centre of which is in the line representing the upper height of breadth of the timber. This sweep describes upwards from the lower part of the top timber.

5th. The *top-timber sweep*, or *back-sweep*, is that which forms the hollow of the top timber. This hollow is, however, very often formed by a mold so placed as to touch the upper breadth-sweep, and pass through the point limiting the half breadth of the top-timber. No attention is paid to these instructions nowadays in framing ship's bodies.

Sweeper. A person appointed to sweep the deck at intervals. *Sweeper of the sky*, a sailor's term for a northwest gale.

Sweep-net. A large draw-net used in fishing.

Sweep-piece. A curved piece of wood fastened to the port-sill, to aid in training a gun.

Sweetening-cock. A cock in the ship's side to admit sea-water into the hold.

Swelchie. A swirling current formed in the Hebrides. A seal.

Swell. The rise and fall of the waves during a calm. A rolling wave, the result of winds either present, preceding, or following it. The increase in diameter at the muzzle of a gun. The increased size of a mast at the hounds.

Swift, or Swifter. A small rope passed from bar to bar of the capstan. A strong rope passed about a frail boat, to strengthen her. A hawser used to swifter in rigging. The forward shroud. Formerly, in the English service, the after pair of shrouds. To *swifter a ship*, to haul her ashore, or to careen her. To encircle a ship or boat with ropes, to strengthen her. To *swifter the bars*, to pass a swifter around the ends of the capstan-bars, so as to distribute the strain. To *swifter in the rigging*, to tauten slack rigging by passing a hawser through blocks in the rigging 8 or 10 feet from the rail, and through blocks on the opposite side of the deck, and hauling it taut.

Swig. A pull on a rope fast at both ends. A tackle whose falls are not parallel. *To swig off*, to pull a rope that is fast at both ends, by swaying or throwing the weight on the bight of it.

Swill (*Eng.*). A wicker fish-basket. The air-bladder of a fish.

Swim. The air-bladder of a fish. To move in the water by means of fins, or by the hands and feet. To float, or be borne up by the water. Swimming should be taught to all sailors. Men may swim from 10 to 15 miles, and it is on record that the Hellespont has been crossed several times, where it is 20 miles wide.

Swine-fish. The wolf-fish.

Swing. To turn around by action of wind or tide when at anchor. *Swinging ship*, the operation of determining the local deviation of the compass, by bringing the ship's head successively to each point of the compass, and taking bearings of a distant object. See Compass.

Swinging-buoys. A set of buoys planted in a convenient place for swinging ship.

Swinging-boom. A long spar, used at sea to stretch the foot of a lower studding-sail, and in port for the boats to hang on to. It is secured by an iron goose-neck to the fore-channels, is supported by a topping-lift, leading through a block on the fore yard-arm, and is retained in place by forward and after guys, leading to the bowsprit and to the gangway. When not rigged out, the after end lies in an iron crane. It has ladders and pendants hanging from it, to which the boats make fast.

Swipes (*Eng.*). Weak beer issued to sailors.

Swirl. An eddy of wind, or in the water. A knot in timber.

Swish (*Eng.*). The light, driving sea-spray.

Swivel. A link, ring, or pin moving about in a socket. *Swivel-bolt*, a bolt turning about its axis. *Swivel-block*, a block turning on a swivel. *Swivel-gun*, a small gun fixed on a pivot, or swivel. *Swivel-hook*, a hook fixed so as to turn on a swivel. *Swivel rowlock*, a rowlock turning on a swivel. *Swivel-link*, a link in chain fitted to turn about a swivel, so as to keep it free from turns. They are placed in each length of 15 fathoms of a cable. *Swivel-eyed*, cross-eyed.

Swona Wells (*Eng.*). Whirlpools near Swona Island.

Sword-fish. The *Xiphias gladius*, a fish of the *Scomberidæ*, or mackerel family, having a long, pointed, sword-shaped upper jaw.

Sword-knot. A gilded knot worn on the sword-hilt. See Uniform.

Sword-mat. A mat made of rope-yarns, by weaving them closely, used for chafing-gear.

Sydney, the capital of the British colony of New South Wales, in Australia, is situated on the southern shores of Port Jackson, 5 miles from the entrance of the harbor. The harbor is quite landlocked, with deep water to the edge of its rocky shores. It has 2 large dry-docks, an observatory, several parks, and a museum. It has an extensive commerce, and a regular line of steam-packets ply between Sydney, Wellington (New Zealand), and Panama. Lat. 33° 51′ S.; lon. 151° 11′ 42″ E. Pop. 136,000.

Sympiesometer. An instrument for measuring the weight of the atmosphere by the compression of gas. Hydrogen gas is generally used.

Syphering. Lapping the chambered edges of planks so as to form a plane surface.

Syzygy (Gr. *suzugia*, a yoking together; from *sūn* together, *zugon*, a yoke). The position of the sun, earth, and other moving body, when their projections on the plane of the ecliptic are in one line. By the *syzygies* of a planet or of the moon are meant those points of its orbit at which the body is in conjunction or opposition with the sun; the two points when the body appears 90° from the sun being distinguished as the *quadratures*. "The moon in syzygy" expresses the position both of conjunction and opposition, the times both of new and full moon; and the term, consequently, is a very handy and appropriate one in speaking of the tides.

Syzygy Tide. The tide which takes place on the afternoon of the day the sun and moon are in syzygy: if the syzygy takes place when the sun or moon is on the meridian, the tide is particularized as the *meridional syzygy tide*.

T.

T. Abbreviation for *the* in the U. S. General Service Signal Code. In the log-book, *t* indicates *thunder*.

Taberin. A species of shark found in the neighborhood of Ceylon.

Tabernacle. An attachment to the mast of a river-boat by which it can be lowered when passing under a bridge.

Table. An arrangement of numbers expressing the data of the motions and positions of heavenly bodies, by the aid of which computations in astronomy and navigation are made.

Table-cloth. The name given to the white, fleecy clouds which sometimes hang over the "table" or flat top of Table Mountain at the Cape of Good Hope, indicating the approach of a southeast gale.

Table-money. An allowance received by the higher grades of officers in some navies with which to furnish their tables.

Table-shore. A low, flat shore.

Tabling. A broad hem on the edges of a sail to which the roping is sewed; also, a method of securing two planks by alternate projections and depressions.

Tack. The lower corner of the luff of a fore-and-aft sail. The rope by which the outer lower corner of a studding-sail is hauled out to the boom. The purchase by which the weather lower corner of a course is confined. To change the direction of a vessel from one tack to another when close-hauled, by bringing the head into the wind and causing it to fall off with the wind on the other bow, by using the helm and sails. A vessel is on the *starboard tack* when the wind blows against the starboard side, but on the *port tack* when the wind is on the port side. *Tack and half-tack*, a long and short tack. *Rise tacks and sheets!* An order given in tacking a square-rigged vessel, at which the tacks and sheets of the courses are let go and the clews hauled up. The expression *not to start tack or sheet* means that no sail is taken in. When applied to a person it implies a resolution not to move.

TACK-BLOCK. The block through which a tack reeves.

Tackles. Combinations of ropes and blocks used as a mechanical power for moving or hoisting heavy weights.

They are variously applied on shipboard for sending aloft masts and yards, hoisting, setting, or taking in sails, setting up or tightening the rigging by which the masts are supported, and in moving guns, anchors, etc.

The necessities for the application of this power are constant, and it is by its use that a limited number of persons are able to control the force of wind and sea which is exerted upon a vessel.

A block consists of the *shell* or outside framework, either of wood or iron, in which the sheaves or pulleys are secured by an iron pin passing through their centres, over which the rope or *fall* passes. The most simple form of a tackle is that in which only a single fixed block is used. In this case there is no gain in lifting power, as the power applied to the rope on one side of the block must be equal to the weight on the other side in order to sustain it. The advantage gained, however, is that the power can be more effectively applied.

If the single block be attached to the weight to be raised, one end of the rope being secured and the power applied to the other end, the lifting power is doubled, for the weight is then sustained by two parts of the rope, each of which bears an equal strain.

Let the rope be passed through another fixed block; the lifting power of the tackle remains the same, but greater convenience and effect is obtained in the application of the power, or, the men who pull upon the rope.

It is then evident that the ratio of the lifting power of a tackle to the applied power depends upon the number of parts of rope which are connected with the movable block, while stationary blocks serve only to give direction or *lead* to the rope, or a more effective application of the power.

If the standing-part of the fall is fastened to the movable block, the advantage of one more part is obtained, and in order to exert the greatest amount of power with a tackle, that block should be applied to the weight which contains the greatest number of parts of the rope.

To ascertain the power which it is necessary to apply to a tackle in order to sustain a certain weight, *divide the weight by the number of parts of rope attached to the movable block*, or $P = \frac{W}{n}$.

Thus far the weight has been considered only as sustained or balanced by the power applied to the fall. If the weight is raised by such an increase in the applied power as shall set the sheaves in motion, the important element of *friction* must be considered in calculating the amount of power which it is necessary to apply in raising a certain weight.

On account of friction, the amount of tension upon each part of the rope will differ. The *hauling-part*, having the friction of all the sheaves to overcome, will bear the greatest strain; while the *standing-part* will have only its proportional part of the weight to sustain. Each intermediate part will also sustain its own proportional part of the weight, increased by the friction of each sheave between it and the standing-part.

The ratio which the friction of a pulley bears to the weight or pressure cannot be determined with any degree of accuracy on account of the great diversity of conditions in the material which is used; as, for example, the material of

which the rope is made,—its flexibility, state of dryness, whether tarred or untarred, etc.; also the materials of which the sheave and pin are made, and the relative diameter of each. It is known, however, that the friction of the pulley follows in all respects the laws by which the friction of sliding bodies is governed, which are, 1st. With the same materials and under the same conditions a constant ratio exists between the pressure of the surfaces in contact and the friction. 2d. With the same pressure and under the same conditions of surface the amount of friction is independent of the extent of surface. 3d. Friction is independent of the velocity of independent motion.

The friction of the pulley is greater than that produced by rolling bodies, and less than that of sliding bodies. It has been estimated that one-sixth of the power gained by each sheave is expended in overcoming friction, and the common rule is that the hauling-part of a fall bears double the strain of the standing-part when raising a weight. This estimate is, however, greatly reduced by the application of rollers to the sheaves of patent blocks. Loss of time is involved in any increase of power; or, *the velocity with which the applied power moves is to the velocity with which the weight rises as the number of parts of rope at the movable block is to unity.* Upon this law the convenience of using tackles of great lifting power often depends. The amount of power that may be applied—that is, the number of men that can be placed at the fall—may generally, within certain limits, be considered a known quantity, and upon this depends, in a great degree, the required power of a tackle, and hence the time in which a body can be lifted or moved. The inconveniences which arise from tackles of great power are loss of time and accumulation of fall by which the deck of a vessel would be encumbered.

Tackles of different sizes and power are used for the various purposes on shipboard, and they are generally named from the particular uses to which they are applied.

A single whip has one single fixed block.

A gun-tackle purchase consists of two single blocks.

A luff-tackle has a double and single block.

A twofold purchase consists of two double blocks, *a threefold purchase* of two treble blocks, etc.

A boom-jigger has usually a double and single block, and is used for rigging studding-sail-booms in and out on the lower yards.

A boom-tackle is a double purchase, and is used in fore-and-aft rigged vessels in guying out the main-boom over the quarter of the vessel with a fair wind.

A deck-tackle is a heavy double purchase used in heavy work about the deck, such as hauling in the cable, etc.

A fish-tackle is a heavy double purchase used in fishing the anchor.

A fore-and-aft tackle is used for stretching the backbone of an awning in spreading it. Any tackle may be thus designated, when for a special purpose it is used in a direction with the length of the vessel.

A griolet-purchase is used for dismounting guns on a covered deck. It consists of two tackles, called the muzzle-purchase and breech-purchase. The lower block of the former consists of a short cylindrical block of wood, one end of which fits into the muzzle of the gun, while sheaves are placed in the outer end. The lower block of the breech-purchase has connected with it a shackle which fits into the jaws of the cascabel. The upper blocks of both tackles are of iron, and have three sheaves.

A hatch-tackle is a small purchase used for hoisting articles from the store-rooms.

A jeer-tackle is a heavy purchase used in sending lower-yards up and down. By a recent improvement the upper jeer-block is connected with and forms a part of the slings of the yard, the chain being attached to the base of the block by a *slip-link.* This block being unwieldy from its size and weight is thus always hooked in place, and there is no loss of time in sending it aloft when required for use.

A jigger is a small tackle used for various purposes.

A rigging-luff, used in setting up rigging, has two single blocks.

A pennant-tackle is composed of a double and single block. It is kept hooked to the pennant under the top, and is used in staying the mast, steadying it in case of injury to the rigging, and other purposes.

A port-tackle is used in tricing up a lower-deck port of a ship of war.

A reef-tackle is used in reefing a topsail or a course.

Relieving-tackles are hooked to the tiller in order to relieve the wheel-ropes in heavy weather, when a great strain is brought upon them; or to steer the ship in case the wheel-ropes are injured in action.

A rolling-tackle is hooked to the quarter of a lower- or topsail-yard and to the mast, in order to relieve the strain of the yard upon the truss or parrel when the vessel is rolling heavily.

A rudder-tackle hooks to the rudder-pennants, by which a vessel may be steered in case of injury to the rudder-head.

A sail-tackle is the purchase used in hoisting a topsail from the deck to its yard in bending.

A side-tackle is used in running out a broadside gun. It consists of a double and single composition block, the latter being the movable block.

A stay-tackle is a heavy double purchase which is hooked to the triatic stay in hoisting out heavy boats.

A Spanish burton is a purchase much used in merchant vessels for handling cargo. The *single* Spanish burton has two single blocks. The leading-part of the fall comes from the lower or movable block, the standing-part leads from the upper or stationary block and is secured to the lower block, while the hook by which the burton is connected with the weight is fastened to the bight of the rope between the two blocks.

The double Spanish burton consists of one double and two single blocks, by which the lifting power is five times greater than the applied power.

A stock-and-bill tackle is a small tackle used in securing anchors for sea.

A tack-tackle is a heavy double purchase, sometimes used in setting the tack or weather clew of a course.

A top burton is a tackle generally used in the tops, but is of sufficient length for the lower

block and end of the fall to reach the deck. It is kept hooked to the pendant at the mast-head, and has the purchase of a luff-tackle, or a double and a single block. A fiddle-block is used in place of the double block, on account of the narrow space between the rigging and the mast-head.

A top-tackle is a heavy double purchase used in sending a topmast up or down.

A train-tackle is hooked to the rear of a broadside gun-carriage and an eye-bolt amidships, serving to run the gun in and prevent it from running out while being loaded. Two training-tackles are used in pointing a gun mounted on a pivot-carriage.

A watch-tackle is a small tackle convenient for any use as a jigger. The double block is usually fitted with a tail in place of a hook.

A winding-tackle is a purchase consisting of a double and single block, or two double blocks. It is used in hoisting heavy weights, being hooked to the eye of a top-pendant or other convenient rope at one of the lower yard-arms. The pendant, being rove through a block at the mast-head, is secured to the deck near the mast, and serves as a support to the yard-arm.

A yard-tackle is a heavy tackle hooked to a lower-yard and used in hoisting heavy weights. It is thus named to distinguish it from the stay-tackle, which is hooked to the stay.—*E. T. Strong, Lieutenant U.S.N.*

Tack-pin. A long belaying-pin used at the fife-rail.

Tack, Thumb-. A tack with a broad, flat head for attaching paper to a drawing-board.

Tactics. See NAVAL TACTICS.

Taffia. A kind of spirits distilled from molasses at Mauritius.

Taffrail. The rail about a vessel's stern.

Tail. A rope spliced around a block with an end of sufficient length to secure it to another rope, instead of a hook. A *tail-block* is a block strapped with a tail, which may be used as a leading block. A vessel *tails* inshore, offshore, up-stream or down-stream, when, being at anchor, her stern tends in that direction. *The tail of a gale* is the latter part of the gale, after the wind has commenced to moderate. *To tail on to a rope* is to man it. *To tail one rope on to another* is to bend or tie them together.

Tailor. A kind of fish resembling the shad, but inferior to it in size and flavor.

Tail-race. The disturbed water after leaving the paddles of a steamer. The channel that carries off the water from a water-wheel.

Tail-tackle. A watch-tackle.

Tail-up. Said of a whale when it shows its tail in diving. Also called *fluking*.

Tail-valve. A small auxiliary valve to aid in starting a large steam-engine by admitting steam to a cylinder when excluded by the main or cut-off valves. *Starting-valve* and *pass-over valve* are synonymous terms.

Taiste (*Eng.*). A name for the black guillemot.

Take. A take of fish is the amount that is caught at a single cast of the net. *To take a departure* is to observe the bearing and distance of a point of land, light-house, etc., before losing sight of the land. *To take in sail* is to reduce sail. *To take an observation* is to observe the altitude of a heavenly body for obtaining the latitude or longitude. *To take in water* is to ship water over the rail. The decrease of tides from the spring-tides is called their *taking off*.

Takel (*Ang.-Sax.*). An ancient name for the arrows which were supplied to vessels.

Take-up. A contrivance for adjusting the length of a connection between two points. The object may be accomplished by moving a bolt or pin from one of a series of holes to another; by a series of hooks; or by a *turnbuckle*, etc. A leak in a steam-boiler, or other vessel, is said to "take-up" when it stops, without manipulation, by the action of temperature, pressure, filling in of foreign matter, or corrosion.

Talero. A silver Venetian coin, equal in value to $1.00.

Tallant. The upper part of a rudder.

Tall Ship. A lofty ship; a former name for a square-rigged vessel.

Tang, or Tangle. A kind of sea-weed.

Tangent-screw. A screw acting at a tangent to the arc of a circle, by which a gradual motion may be given to a limb passing over the arc.

Tang-fish. A Scotch name for the seal.

Tangier, the diplomatic capital of Morocco, is situated near the western entrance of the Strait of Gibraltar, southeast of Cape Spartel, in lat. 35° 47′ 12″ N., lon. 5° 48′ 30″ W. It presents a very striking appearance from the sea, as it stands on a height near a spacious bay, and rises in the form of an amphitheatre. It is surrounded by walls, and defended by a castle and several forts. The harbor, which was once capacious and protected by a mole, was formerly frequented by vessels from nearly all maritime nations, but is now neglected, and the trade is confined chiefly to Gibraltar and the Spanish coast. Pop. 15,000.

Tangles. An instrument used in dredging, for obtaining the more minute forms of animal life from the bottom of the sea.

Tank. An iron structure for holding fresh water. It is cubical in shape, and usually contains about 600 gallons. A circular hole in the top, called a man-hole, is of sufficient size to admit a person for the purpose of cleaning and whitewashing. Small copper tanks are placed in the magazine for the stowage of powder. See POWDER-TANK.

TANK-TOGGLE. A short stout piece of wood placed inside the man-hole of a tank when it is to be hoisted, serving as a place to which the tackle can be attached.

Tanka. A covered Chinese row-boat, used in taking passengers to and from vessels.

Tanned Sails. Sails soaked in oak-bark.

Tap. A piece of tempered steel having an exterior screw-thread upon its surface, a portion of which is cut away by longitudinal grooves, for cutting interior or *female* screw-threads. It is provided with a square head for receiving a wrench. An orifice for withdrawing a fluid from a pipe, chamber, or reservoir. *To tap a buoy*, to empty the water from a buoy which has leaked in, causing it to float low in the water; to *bleed* a buoy. *To tap the admiral* (*Eng.*), an expression applied to a person who is willing to drink anything that he can obtain,—referring to the story of the theft of spirits from the cask containing the dead body of an English admiral.

Taper. To reduce the size of a rope to a point at the end, by cutting out the rope-yarns as required.

Tapered Cleat. A piece of timber bolted under beams to support them, in place of stanchions.

Tappet. In machinery, an arm or lever which is moved periodically by contact with a pin, roller, or other piece having a reciprocating motion; as, the *tappets* which actuate the steam-valves of the Cornish pumping-engine and other steam-pumps.

TAPPET-MOTION. A term applied to the valve-gear of a steam-engine when the valves are actuated by *tappets*.

Tar. A thick resinous substance obtained from pine wood, used upon rope to protect it from the weather and prevent dampness from penetrating among the fibres. Also, to cover or smear with tar. *Tar and feather*, an illegal mode of punishment, occasionally resorted to in extreme cases. During the reign of Richard I. of England it was a legal punishment for theft in the British navy. A sailor is sometimes called a *tar*.

TARBRUSH. *A touch of the tarbrush*, a description of the color of a person of mixed blood. *Tarred with the same brush*, said of men of a similar character; synonymous with "Birds of a feather."

TARRED LINE. Line to which tar has been applied.

Tarragona, a seaport city of Spain, is principally built upon a large rock at the mouth of the Francoli, in the Mediterranean. It is divided into two sections, an upper and lower town; is inclosed by walls and ramparts, and defended by two castles. Among the principal buildings are the academies of design and naval architecture. It has manufactures of coarse cloth, hats, barrels, etc., and a large export trade in wine, brandy, nuts, and cork. Pop. 19,000.

Tarbet. A Scotch name for a low spit of land dividing a lake from the sea.

Target. A mark for great gun or small-arm practice. The regulation target for great guns consists of a frame-work, made by two boards crossing at right angles, through the centre of which is secured an upright mast about 12 feet in height. Small ropes connecting the upper end of the mast with the ends of the crossed boards serve as stays, upon which the four triangular sails of the target are set. The target, when ready for use, is of the form of a pyramid. A small-arm target is of sheet-iron, having painted on its face the different inclosed squares by which the shots may be scored.

TARGET-FRAME. See TARGET.

TARGET-PRACTICE. The quarterly exercise of the crew of a vessel in firing at a target either with great guns or small-arms.

Targia. The ancient name for the *tartan*, a small vessel used in the Mediterranean.

Tarita. An ancient term for a vessel carrying a cargo.

Tarn (*Scotch*). A small mountain lake.

Tarpaulin. Canvas painted to render it waterproof, used as a covering for hatches, etc. Tar was formerly used instead of paint. Painted hats and coats for bad weather are also called tarpaulins.

Tarrock. A kind of gull (*Larus tridactylus*).

Tartan. A coasting vessel of small size, used in the Mediterranean. It carries one mast, upon which a lateen-sail is set.

Tartar. A commander with a bad temper. *To catch a tartar* is to mistake the force of an enemy and be obliged to surrender.

Task (*Eng.*). To examine a vessel regarding the soundness of her timbers. A timber is *tasked* by cutting or boring it with an auger to ascertain its condition.

Tasman, Abel Janssen. Exploring the coast of New Holland under instructions from Van Diemen, this Dutch navigator came (December 1, 1642) upon the island south of Australia, to which he gave the name of his patron, but which is now called Tasmania. Pursuing his investigations in the Southern Atlantic, he discovered New Zealand, and a group of islands then unknown to geographers.

Tasting Timber. Chipping it with the adze, or boring it with the auger, for the purpose of ascertaining its quality or defects.

Tattoo. The evening drum-beat before "piping down." To mark the body with indelible inks or dyes.

Taunt. Tall, as applied to the masts of a vessel.

Taurus, Constellation of (*Lat.* "The Bull"). The second constellation of the ancient zodiac, lying between Aries and Gemini. This group is easily identified in the heavens, as it contains the two beautiful little clusters of minute stars called the *Hyades* and the *Pleiades;* in the former is situated the bright ruddy star *α Tauri.* A line joining Aldebaran and Sirius is bisected by the middle star of Orion's Belt. *α Tauri*, Aldebaran; *β Tauri*, Nath; *η Tauri*, Alcyone.

Taurus, Sign of. The second division of the ecliptic, including from 30° to 60° of longitude. Owing to the precession of the equinoxes, the *constellation* Taurus is no longer in the *sign* of that name, the constellation Aries having taken its place. The sun is in Taurus from about April 20 to about May 21. Symbol ♉.

Taut (Ang.-Sax. *tought*). Tight, said of a rope. *On a taut bowline*, said of a ship when close-hauled, as the bowlines are then taut. *A taut hand*, a firm hand in matters of discipline. *Taut weather helm*, or *taut helm*, is caused by the trim of a vessel, or by want of balance of sail, by which the quality of ardency is given to the vessel. *Taut leech*, said of a sail when hoisted so as to make the leeches taut.

Taylor, J. Winthrop, Surgeon-General U.S.N. Born in New York. Appointed from New Jersey, March 7, 1838; entered the service as assistant surgeon; attached to sloop "Erie," West India Squadron, 1838–40; sloop "Marion," West India Squadron, 1842–43; sloop "John Adams," Home Squadron, 1845–48; receiving-ship, Boston, 1850; sloop "Dale," 1851–53.

Commissioned as surgeon, May 1, 1852; rendezvous, New York, 1854–56; sloop "St. Mary's," 1856–59; steam-sloop "Pensacola," West Gulf Blockading Squadron, 1861–63; naval rendezvous, Boston, 1864–66; fleet-surgeon, Gulf Squadron, 1866–67; fleet-surgeon, North Pacific Squadron, 1868–69; Naval Hospital, Chelsea, 1870–72; naval rendezvous, Boston, 1873–77; chief of the Bureau of Medicine and Surgery, 1878–79. Retired August 25, 1879; died January 19, 1880.

Taylor, William Rogers, Rear-Admiral U.S.N. Appointed midshipman, April 1, 1828. Promoted to passed midshipman, June 14, 1834.

Promoted to lieutenant, February 10, 1840.
Promoted to commander, September 14, 1855.
Promoted to captain, July 16, 1862.
Promoted to commodore, July 25, 1866.
Promoted to rear-admiral, January 19, 1871.
Retired by law, having attained the age of 62 years, November 7, 1873.

As midshipman he served on board the frigate "Hudson" and the sloop-of-war "Vandalia," on the coast of Brazil, from 1828–31, and on board the sloop-of-war "Peacock," on the coast of Brazil, in 1832.

As passed midshipman, on board the sloop-of-war "Peacock," in 1835 and 1836, in the East Indies.

As acting lieutenant, on board the schooner "Enterprise," in the East Indies and the Pacific Ocean, in 1836–37, and on board the line-of-battle ship "North Carolina," in the Pacific, in 1837–38.

As lieutenant, on board the steamer "Poinsett" and the brig "Oregon," engaged in a survey of Tampa Bay, under command of Lieut. L. M. Powell, in 1842–43. During a portion of that time he was in command of each of those vessels. Brig "Perry," on the coast of Brazil, in 1843–44; and the line-of-battle ship "Columbus," on the coast of Brazil, in 1844; sloop-of-war "St. Mary's,'" in the Gulf of Mexico during the Mexican war, in 1845–46; frigate "St. Lawrence," in the North Sea, in 1847; sloop-of-war "Albany," in the West Indies, in 1849–50; sloop-of-war "Saratoga," in the Atlantic Ocean, in 1855, from which ship he was detached for promotion.

As commander, he was ordered to the ship "Housatonic," but before sailing was promoted to captain.

As captain, in command of the "Housatonic," in the South Atlantic Blockading Squadron, in 1862–63; as fleet-captain with Admiral Dahlgren in 1863; and in command of the ship "Juniata," in the North Atlantic Blockading Squadron, in 1864.

As commodore, in command of the North Squadron of the Pacific Fleet in 1869–71, when he was detached on promotion.

As rear-admiral, in command of the South Atlantic Station in 1872–73, from which duty he was detached on being retired by law.

His duties on shore during his early naval life were performed at navy-yards, receiving-ships, the Naval Observatory, and the Naval Asylum. He was president of a board to revise and modify a code of regulations for the navy in 1863–64. In 1865–66, he was in charge of the ordnance-yard at Washington, then a branch of the Bureau of Ordnance. His total amount of bureau duty was 9 years and 5 months, as lieutenant, commander, captain, and commodore, embracing work at Alger's, Cold Spring, Tredegar, Bellona, Fort Pitt, and Hickory and Williams's foundries, and the foundries at Reading, Pa., and at Portland, Me.; in the Bureau of Ordnance, at the powder-works near Dover, N. H., and at South Acton, Mass., and at the Boston Navy-Yard.

On the assassination of President Lincoln, he was appointed one of a guard of honor to escort his remains from Washington to Springfield, Ill.

In 1868, he was a member of a board for the examination of officers for promotion; and in 1871–72, he was president of the Naval Board for examination and retirement, at the Navy Department.

The principal events of his naval life were as follows: When the "Peacock" was stranded on the island of Mazira, in 1836, he was sent in command of a cutter to convey Edmund Roberts, a diplomatic agent of the United States, from the ship to the port of Muscat, with the ratified copies of some treaties, which he was commissioned to exchange. The boat was single-banked, and pulled 5 oars; the voyage lasted about 5 days, and was not a perfectly safe one. At Muscat, he was invited by the imaum to take under his orders a sloop-of-war called the "Sultané," mounting 16 guns, and proceed to the relief of the "Peacock"; that ship had, however, in the mean time, been got off, and he fell in with her at sea.

On the 8th and the 15th June, 1846, the "St. Mary's" engaged a battery near the point at Tampico Bar, and he commanded the first division of guns on both occasions.

At the surrender of Tampico to Commodore Connor, he commanded the "St. Mary's" launch, which was a part of the attacking force.

During the siege of Vera Cruz, he commanded an 8-inch gun in the naval battery for 36 hours.

During the blockade of Charleston, he happened to be senior officer off that port when the rebel rams "Chocura" and "Palmetto" attacked the squadron, in January, 1863. He engaged one of them with the "Housatonic," but she withdrew over the bar. His ship formed part of the reserve fleet when Admiral Dupont made his attack upon the Charleston forts. When Admiral Dahlgren relieved Admiral Dupont, he was appointed fleet-captain, and served with Dahlgren in all the operations against Morris Island, from July 10 to the 19th, 1863. On the 16th he was in battle with him on board the monitor "Catskill," and again, on the 18th, in the monitor "Montauk."

On the 24th and 25th December, 1864, he commanded the "Juniata" in the attack upon Fort Fisher.

Admiral Taylor was a member of the Board of Visitors to attend the graduation of the class of midshipmen at the Naval Academy in June, 1860, and in January, 1872, he was president of the Board of Visitors to attend the graduation of the class at the Torpedo Station.

Teach. A term applied to the direction that any line points out.

Teak. A tree (*Tectonia grandis*) of East Indian growth, valuable for ship-timber.

Teal. A small wild duck of the species *Querquedula crecca.*

Team-boat. A side-wheel ferry-boat worked by horse-power.

Tea-wagon. An old name for the British East India Company's ships, tea constituting the greater part of their homeward-bound cargo.

Teazed Oakum (*Eng.*). Oakum prepared for use in calking.

Teeth. A fanciful name sometimes given to the guns of a vessel. It was more applicable to the batteries displayed by a ship of the line than to ships of more modern construction.

Telegraph-cables. The idea of submarine communication by means of electricity was entertained by some of the earliest electricians, but

no practical use was made of the discoveries in that direction until, by the inventions of Professor Morse in 1836, apparatus for the recording of telegraphic messages was introduced, and the practicability of communication by this means established.

Don Francisco Salva is said to have proposed the laying of a submarine cable between Barcelona and Palma, a port on the island of Majorca, in 1797, but the first cable or wire upon which experiments were actually made was constructed and operated by Dr. O'Shaughnessy, near Calcutta, in 1839. The wire was 21 miles in length, and insulated by a covering of tarred yarns, over which split rattan was placed, and over the rattan another covering of tarred yarns.

Professor Wheatstone, in 1840, before a committee of the English House of Commons, asserted the practicability of laying and operating a submarine cable between England and France, and in 1842 successful experiments were made by Professor Morse with a copper wire submerged between New York and Governor's Island, which was insulated by winding it with a hemp strand covered with a compound of tar, pitch, and india-rubber.

In a letter addressed to the Secretary of the Treasury by Professor Morse, in 1843, he said that, judging from his experiments of the previous year, telegraphic communication could with certainty be established across the Atlantic. In 1843, Samuel Colt also laid a wire from Fire Island to New York City, which was successfully used.

Experiments for the more perfect insulation of submarine cables followed these trials, and in 1845 a process of preparing gutta-percha for this purpose was patented in England, which material has been extensively used in the manufacture of submarine cables since that time. Its first use was upon a cable one-half of a mile in length, which was laid under the Rhine between Dentz and Cologne, and in 1846 a wire covered with the same material was laid between New York and Jersey City.

In 1850 a cable was laid across the Strait of Dover, 27 miles in length, from Dover to Cape Grinez. This was the first cable laid in the open sea, and it failed to transmit messages after the first day of its completion. Another was laid in the following year between Dover and Calais, which contained four conducting wires, each of which was insulated with gutta-percha, and these were covered with a layer of hemp, steeped in a solution of tar and tallow. In 1853 a cable 80 miles in length was laid between Dover and Ostend, which contained 6 conducting wires and weighed 5¾ tons per mile. In 1853 England and Holland were connected by a single insulated wire, 120 miles in length, weighing 1¾ tons per mile, which was in use for 12 years. From this time the use of submarine cables in connection with shore lines of telegraph-wires greatly increased, so that between 1853 and 1858 37 cables of various extents had been laid in Europe and its adjacent waters, with a total length of 3700 miles.

The brilliant undertaking of uniting America and Europe by a telegraphic cable was first attempted in 1857, and with this and succeeding attempts the name of Cyrus W. Field is inseparably connected. The U. S. S. "Niagara" and H. B. M. S. "Agamemnon" were employed in laying the first cable, but owing to the breaking of the cable the undertaking was not successful. In 1858 another trial was made, and the two parts were successfully united in mid-ocean, and the cable completed August 10. Congratulatory messages were exchanged between Queen Victoria and President Buchanan, and for 23 days the cable continued to transmit messages, although the signals were with difficulty understood, owing to the weakness of the current. At the end of this time the transmission of intelligible messages entirely failed, and the cable was finally abandoned. This cable was composed of 7 conducting wires,—6 laid around 1 central wire,—covered with 3 layers of gutta-percha. Outside of this a layer of tarred hemp was placed, and the whole surrounded by 18 strands of charcoal wire, each strand being composed of 7 wires, —6 laid around 1 central wire. The whole cost of this enterprise amounted to $1,834,500.

After this failure steps were taken for the laying of a cable from Labrador to Scotland, by way of Greenland, Iceland, and the Faroe Islands, and in 1860 soundings were taken of the proposed route by an English ship of war, and examinations made of the different coasts for the purpose of obtaining practicable landing-places for the ends of the cables. The required length by this route is 1800 miles, which could be divided into three sections of about 600 miles each. Although favorable reports of the feasibility of this route were made, no further steps were taken.

In 1862, Mr. Field again visited England, in order to make arrangements for carrying out his original design, which resulted in a third attempt to lay a cable between the coasts of Ireland and Newfoundland in 1864–65. The steamship "Great Eastern" was employed in this undertaking, but another failure was experienced on account of the breaking of the cable and the inability to recover the end. During the year 1866 another cable was laid by the same steamer, which was successfully completed July 27, and the cable of 1865 was also recovered and united, thus forming two lines of communication between Europe and America.

These cables lasted but about 8½ years, and in 1873 and 1874 two others, similar in construction, were laid, the work being successfully accomplished by the "Great Eastern," assisted by three smaller vessels. The work of laying the former was commenced June 16, 1873, and on June 27 the western end was landed at Heart's Content, 1700 miles having been payed out in 11 days. The latter extended from Ballenskilling's Bay, Ireland, to Nova Scotia, and thence to Rye, N. H., and was not completed until early in the summer of 1875.

In 1869 a cable was laid by the "Great Eastern" between Brest, France, and the island of St. Pierre, near the Gulf of St. Lawrence, and thence to Duxbury, Mass. The entire length of the two sections of the cable is 3047 miles. The weight of the section between Brest and St. Pierre is 400 pounds per mile, and that of the western section 107 pounds per mile. The conductor of both sections is composed of 6 copper wires laid around 1 central wire, which are insulated by alternate layers of gutta-percha and Chatterton's compound, covered with a coating

of tarred jute-yarns. Outside of this core galvanized iron wire, covered with manilla steeped in tar, is placed next a coating of mineral pitch and silica, called Clark's compound, and outside of all a layer of galvanized iron wire.

A cable was laid between the coasts of Ireland and Newfoundland in 1879, followed by another in the present year, in which the cores consist of homogeneous iron wires covered with two coats of yarn, pitch, and silica. During the past 20 years telegraphic cables have been laid in all parts of the world, and it is estimated that, at the present time, their total length is about 231,000 miles. Among the principal ones is that from Malta to Alexandria, Egypt, laid in 1861, 1518 miles long; the Persian Gulf cable, in 1864, 1330 miles long; the direct cable from Malta to Alexandria, in 1868, 1053 miles long; from Suez to Aden, 1460 miles; from Aden to Bombay, 1818 miles; and from Gibraltar to Malta, 1120 miles, in 1870. The completion of the China cable, in 1871, terminating in Japan, which, with its branches, connect the principal ports of China, Australia, and adjacent islands with western Europe; also the cables of the West India and Panama Company, 2613 miles long, the Panama and South Pacific cable, 1100 miles long, and that which connects the Windward Islands with Demerara during the same year; from Pernambuco to Para, in 1873, 1080 miles long; and from Lisbon to Madeira, in 1873, which, in 1874, was extended to Cape St. Vincent, on one of the Cape de Verd Islands, 1260 miles, and thence to Pernambuco, Brazil, 1953 miles. From these and other main lines of cables branches extend, in connection with shore lines of telegraph-wires, so that nearly all of the principal inland cities and seaports of the world are now in telegraphic communication.—*E. T. Strong, Lieutenant U.S.N.*

Telemeter. An instrument used for determining the distance of an object whose length is known, from its apparent length when seen between the parallel wires of a telescope.

Telescopic Funnel. A steamship smoke-pipe or funnel made in two or more sections, so arranged that one slides within another, in the manner of a telescope, for the purpose of lowering it clear of the sails and rigging when the ship is under sail alone.

Telescopium. See CONSTELLATION.

Tell Off. To count off or select men for a special duty.

Tell-tale. A small compass hanging from the deck overhead with its face downwards. It is generally placed in the cabin, where it can be conveniently referred to by the commanding officer. Also, an attachment to the steering-wheel, showing the position of the tiller. *Tell-tale shake*, the shaking of a rope from aloft as a signal to let it go, in place of hailing from aloft.

Tell that to the Marines! An exclamation of doubt as to the truth of a statement.

Temple, William Grenville, Commodore U.S.N. Born in Vermont, March 23, 1824. Appointed acting midshipman from Vermont, April 18, 1840; ordered to receiving-ship "Columbus," Boston, September 24, 1840; detached from "Columbus" and ordered to frigate "Constellation," Boston; May 8, 1844, detached from "Constellation" at Norfolk, and granted leave of absence; August 21, 1844, ordered to frigate "Potomac," flag-ship of the Home Squadron, Philadelphia; March 14, 1845, detached from "Potomac" at Pensacola, and ordered to brig "Lawrence" at same place; October 21, 1845, detached from "Lawrence" at Pensacola, and ordered back to "Potomac" at same place; December 5, 1845, detached from the "Potomac" at Norfolk, and ordered to Naval School, Annapolis.

Promoted to passed midshipman, July 11, 1846; July 13, 1846, detached from Naval School; October 5, 1846, ordered to sloop-of-war "Boston"; November 15, 1846, wrecked on west end of Eleuthera, one of the Bahamas, opposite Hole-in-the-Wall; November 29, 1846, ordered to Norfolk in schooner "Volant," in charge of sick men from wreck of the "Boston"; January 7, 1847, ordered to receiving-ship "Pennsylvania," Norfolk; February 4, 1847, detached from "Pennsylvania," and ordered to steamer "Scourge," New York; March 29, 1847, present at the surrender of Vera Cruz; March 31, 1847, present at the capture of Alvarado by the "Scourge," and ordered to take command on shore; April 1, 1847, relieved on shore and ordered back to the "Scourge"; April 18, 1847, present at the capture of Tuspan; June 15 and 16, 1847, present at the capture of Tabasco; November 27, 1847, detached from the "Scourge" at Frontera; December 25, 1847, ordered as acting master to the steamer "Mississippi"; April 21, 1848, detached from the "Mississippi"; June 14, 1848, ordered to Naval Observatory, Washington; May 2, 1849, detached from the Observatory, and ordered as acting master to the coast survey schooner "Petrel," New York; transferred at New Orleans into the coast survey steamer "Hetzel"; August 2, 1850, detached from the "Hetzel," and ordered to the Coast Survey Office; October 11, 1850, detached from the coast survey, and ordered to the Observatory; November 28, 1850, detached from the Observatory, and granted leave of absence for the purpose of taking charge of the hydrographic works on the survey of the Isthmus of Tehuantepec, for a railroad and canal; April 5, 1852, ordered as acting master to the sloop-of-war "Levant."

Promoted to master, July 21, 1854.

Promoted to lieutenant, April 18, 1855; May 7, 1855, detached from the "Levant"; June 4, 1855, ordered to the steamer "Corwin," coast survey; December 3, 1855, detached from the "Corwin" and ordered to the Coast Survey Office; May 19, 1856, detached from Coast Survey Office, and ordered to the steamer "Corwin," coast survey; June 1, 1857, succeeded to the command of the "Corwin"; October 11, 1858, detached from command of the "Corwin," and ordered to the Coast Survey Office; April 7, 1859, detached from the Coast Survey Office, and ordered to the steam-frigate "Lancaster," flag-ship of the Pacific Squadron; October 11, 1861, detached from the "Lancaster," and ordered to return to New York; November 11, 1861, ordered to command the steamer "Flambeau"; January 22, 1862, detached from command of the "Flambeau"; February 26, 1862, ordnance duty, New York.

Promoted to lieutenant-commander, July 16, 1862; September 22, 1862, detached from ordnance duty, and ordered to command the steam-gunboat "Pembina," and to join the West Gulf Blockading Squadron; November 22, 1862, de-

tached from command of the "Pembina," and ordered to Key West as fleet-captain of the East Gulf Blockading Squadron; April 10, 1864, ordered temporarily to command the flag-ship "San Jacinto," for special service; April 13, 1864, detached from command of the "San Jacinto," and ordered to resume duty as fleet-captain; July 12, 1864, present on duty in the trenches about Washington, on the occasion of Gen. Early's attack; September 19, 1864, detached from fleet-captaincy, and ordered to ordnance duty at Cold Spring Foundry; November 8, 1864, detached from ordnance duty, and ordered to command the steamer "Pontoosuc," and to join the North Atlantic Blockading Squadron; December 24 and 25, 1864, present at the bombardment of Fort Fisher; January 13 to 15, 1865, present at the capture of Fort Fisher; February 18 to 22, 1865, present at the passage up the Cape Fear River, and the capture of Wilmington, N. C.

Promoted to commander, March 3, 1865; April 1, 1865, present at the bombardment of rebel fortifications on the James River, above Dutch Gap; April 3, 1865, present at the capture of Richmond, Petersburg, etc.; May 25, 1865, detached from command of the "Pontoosuc," Hampton Roads, and granted leave of absence; August 17, 1865, ordered to command the steamer "Tacony," and to join the Atlantic Squadron; October 31, 1866, detached from command of the "Tacony," and ordered as inspector of ordnance to Portsmouth, N. H.; October 18, 1869, detached from ordnance duty at Portsmouth, and ordered as member of Permanent Ordnance Board, at the Navy Department.

Promoted to captain, August 28, 1870; October 18, 1870, detached from ordnance duty, and ordered as assistant judge-advocate of the navy; December 23, 1870, detached from the Navy Department, and ordered to command the frigate "Tennessee"; April 25, 1871, detached from the "Tennessee"; May 1, 1871, ordered to duty under the Bureau of Ordnance; October 5, 1871, detached from ordnance duty, and ordered to flag-ship "Wabash"; July 6, 1872, ordered to command the "Wabash"; May 31, 1873, detached from the "Wabash," with leave of absence for 18 months, and orders to return to the United States at its expiration; December 11, 1874, ordered to take charge of the government's reception of the king of the Hawaiian Islands at Washington, for which service, by permission of Congress, received from his majesty Kalakaua a decoration as Knight Commander of the Royal Order of Kamehameha I.; relieved from this duty on December 28, 1874; February 1, 1875, ordered, as captain of the yard, to New York Navy-Yard; October 31, 1877, detached from New York Navy-Yard, and placed on waiting orders.

Promoted to commodore, June 5, 1878; October 26, 1878, ordered to Montevideo, South America, for temporary duty on board the flag-ship "Hartford"; February 15, 1879, detached and placed on waiting orders; October 22, 1879, member of the Examining and Retiring Board, which is his present duty.

Templet, or Template. A mold in wood, or an iron plate cut to any particular shape by which other materials are shaped.

Temporary Star. One that having become visible, increases gradually in brilliancy and then slowly disappears.

Tench. The *Tinca vulgaris*, a fresh-water fish.

Tender. A small vessel used for giving assistance to a large ship or a flag-ship, as carrying stores or dispatches, transferring men, etc.

Tenon. The shoulder at the end of a piece of timber which fits into a mortice; as, the tenon at the heel of a mast.

Ten-pounder. The name of a fish found in the West Indies.

Teredo Navalis. A worm found in the sea which is very destructive to submerged wood. It is a genus of testaceous mollusks, and has been seen at a depth of 10 fathoms.

Term-piece. A piece of carved work placed upon the stern, extending from the taffrail to the foot-rail of the balcony.

Tern. A sea-bird of the genus *Sterna*, resembling a gull.

Terrada. A large Persian boat.

Terrapin. A large turtle of the genus *Chalonia*, found in salt water.

Tertiate. To examine the thickness of the metal of a gun to ascertain its strength and prove the proportions at different parts.

Test-cock. A cock for withdrawing a small quantity of fluid from a vessel or chamber in which it is confined, for the purpose of observing its condition.

Testone. A former Papal coin, issued in 1785, in value about $0.32.

Testoon. A Portuguese coin, about $0.13 in value.

Tew (*Eng.*). To beat hemp in preparing the fibre.

Thatcher, Henry K., Rear-Admiral U.S.N. Born in Maine, at the seat of his grandfather, Maj.-Gen. Henry Knox, of Revolutionary memory. Appointed midshipman from there, March 4, 1823; Washington Navy-Yard during that year (which was very active in equipping the so-called Mosquito Fleet of Commodore David Porter, to attack the pirates of the West Indies), from thence to frigate "United States," under Commander Isaac Hull, until May, 1827.

Promoted to passed midshipman, March 23, 1829.

Promoted to lieutenant, February 28, 1833; served at various navy-yards and on board different vessels from 1833 to 1855.

Promoted to commander in February, 1855; commanding sloop-of-war "Decatur," Pacific Squadron, from 1855–57; executive-officer, Boston Navy-Yard, 1860–61; commanding sloop-of-war "Constellation," coast of Europe and Mediterranean, 1862–63, as a commander.

Promoted to commodore during this command. Relieved July, 1863, and ordered home to command steam-frigate "Colorado" and division of Southern blockade; commanded first division of Porter's squadron in the attacks and capture of Fort Fisher and dependencies, in December, 1864, and January, 1865; after which he was ordered to command of the West Gulf Squadron as acting rear-admiral, and at once commenced active operations for the capture of Mobile and coast of Texas, in co-operation with the land-forces under Gen. Canby. After a vigorous bombardment, Forts Alexis and Spanish Fort were carried by assault by the army on the night

of April 9, 1865, leaving the minor works a comparatively easy prey,—the Forts Tracy and Huger, near Tracy and Huger, made a spirited resistance until the night of the 11th, when their garrisons made their escape through the marshes and in boats. On the following day flags of truce were discovered at the landing, and the announcement made that the rebel Gen. Maury had evacuated the city with all his army; a formal demand was at once made by Gen. Granger and Acting Rear-Admiral Thatcher for the surrender of the city, which was unconditionally complied with. The rebel naval forces, under Flag-Officer Ebenezer Farrand, consisting of the ironclad frigate "Nashville," sloop-of-war "Morgan" (partially ironclad), the ironclad ram "Baltic," the steamer "Black Warrior," and the rams "Tuscaloosa" and "Huntsville," fled to the river Tombigbee, and sinking the two last named in the channel. Our forces afloat being about to pursue them, Farrand proposed terms of surrender, which having been accepted by Acting Rear-Admiral Thatcher, a suitable force under Commander Edward Simpson (fleet-captain) was dispatched by him to take possession and bring them with their officers and men to the city. In May, 1866, Commodore Thatcher was relieved from the Gulf and ordered to the command of the North Pacific Squadron, in which command he remained until relieved, in August, 1868.

Commissioned as rear-admiral, July 25, 1866; port-admiral, at Portsmouth, N. H., 1869–71. Retired May 26, 1868; died 1880.

Theodolite. An instrument used in surveying, for measuring angles, leveling, etc.

There Away. In that direction.

Thermal Unit. A unit of heat; or, the quantity of heat that will raise a unit of weight of matter through a unit of temperature. The English *thermal unit* is the quantity of heat that will raise one pound of pure water at its maximum density, and temperature of 39.1°, one degree F.

Thermometer. An instrument for indicating comparative temperature. In its common form it consists of a capillary glass tube, hermetically sealed at one end and having a bulb blown at the other, thoroughly filled with mercury or colored alcohol at a higher temperature than the instrument is intended to indicate or is likely to be subjected to, a Torricellian vacuum being formed above the liquid when it contracts to lower temperatures. The tube is attached to an arbitrarily graduated scale, usually that of Celsius, Fahrenheit, or Réaumur, the *range* or expansion of the liquid between the temperature of melting ice and that of boiling water being divided, respectively, into degrees of 100, 180, or 80 parts. The zero of the Celsius (*Centigrade*) and Réaumur scales is the temperature of melting ice; that of Fahreheit, 32° below. In delicate physical investigations an *air thermometer* is employed.

The thermometers in use on shipboard for meteorological purposes are the *dry bulb*, from which the temperature of the air is noted; the *wet bulb*, which, by comparison with the dry bulb, gives the amount of moisture in the atmosphere; and the water thermometer, which is used in obtaining the temperature of sea-water. A *maximum* and *minimum* thermometer is one that regulates the extremes of temperatures. A *deep-sea* thermometer is used to obtain the temperature of sea-water at great depths, and is constructed so as to resist the pressure of water at such depths.

Thick-and-dry for Weighing. An expression indicating that the nippers should be placed close together on the cable, and as dry as possible, to prevent the slipping of the cable when the anchor breaks ground.

Thick-and-thin Block. A block having two sheaves of different sizes, one above the other. Also called a fiddle-block.

Thick-stuff. Planking used in ship-building, between 4 inches and 1 foot in thickness.

Thieves' Cat (*Eng.*). A cat-o'-nine-tails with knots upon the lashes, which is applied as a punishment for theft.

Thimble. An iron ring, the outer surface of which is concave in order that it may be held in position by a rope when spliced around it. It thus serves as a lining for the rope, and protects it from the chafe of a hook or other thimble.

A *lock-thimble* is formed by two thimbles which are interlocked.

THIMBLE-EYES. Holes shaped like thimbles made in an iron plate; formerly used in place of dead-eyes for setting up topmast rigging.

Thokes (*Eng.*). Fish with broken bellies, which are not allowed to be packed with the unbroken, or *tale* fish.

Thole, or Thole-pin. A pin, either of wood or metal, fixed to the gunwale of a boat to retain the oar in place when rowing, and which serves as the fulcrum of the lever. The oar may be placed between two such pins, or secured to a single pin by means of a grommet.

Thorn-back. The fish *Raia clavata.*

Thorough-foot. The disarrangement in the parts of a tackle-fall caused by turning or capsizing one of the blocks through the parts.

Thorough-put. A *thorough-foot* (which see).

Thrasher. The shark *Carcharias vulpes.* The name is also applied to the grampus on account of its supposed mode of attack with its tail.

Thread. To follow the course of a narrow, tortuous channel.

Three-cocked-hat. An old style of hat formerly worn by naval officers.

Three-decker. A ship fitted for carrying guns upon three decks.

Three Half-hitches are more than a King's Yacht wants is an exclamation peculiar to the English service, meaning that two are enough for any purpose.

Three Sheets in the Wind is descriptive of the condition of a person partially intoxicated.

Three Sisters (*Eng.*). The three rattans formerly carried by the master-at-arms and boatswain's mate.

Three-square. A surface bounded by three sides; as, a three-cornered sail.

Thrift (*Eng.*). The *Armeria*, a plant found near the coast.

Throat. That part of a gaff which is next to the mast. Also applied in ship-building to the midship portion of the floor-timbers, knees, breast-hooks, etc.

THROAT-BOLT. An eye-bolt either on the throat of a gaff or under the top, into which the throat-halliards are hooked.

THROAT-BRAIL. One of the ropes or brails by

which a trysail or spencer is gathered up to the throat of the gaff when the sail is taken in.

THROAT-HALLIARDS. The tackle by which the throat of a gaff is hoisted.

THROAT-SEIZING. The seizing nearest the dead-eye, connecting the end part of a shroud or backstay with the standing part. Also, the seizing by which the strap of a block is made to fit into its score.

Throttle-valve. A valve situated in the steam-pipe for regulating the admission of steam to an engine. It generally consists of a disk arranged to rotate about one of its diameters, the *throttle-valve-stem*, or axis, being attached to suitable levers and handles.

Through All. Sail is carried "*through all*" when it is not reduced to a squall. Formerly, when the anchor was weighed by means of a messenger, the cable was said to "heave through all" when the nippers, being wet and slippery, did not secure the cable to the messenger.

Through-bolt. A bolt which is driven through and through the sides of the ship, and is riveted on the inside upon clinch-rings.

Through-fastening. A bolt passing through timber and planking.

Through the Fleet. A former mode of punishment in the English navy, sometimes given for serious offenses, in which the offender was towed to each vessel in the fleet, where he received a part of the lashes to which he had been sentenced.

Thrums. Short bits of rope-yarns used in making mats. A *thrummed mat* is made by sewing short pieces of yarns to one side of a piece of canvas or heavy cloth, and is used in protecting sails and rigging from chafe.

Thrust. A force which acts between two contiguous bodies, or parts of a body, when each pushes the other from itself, and which tends to *compress* or shorten each body on which it acts in the direction of its action. It is the kind of force which is exerted by a fluid tending to expand against the bodies which surround it.

THRUST-BEARING. A bearing that receives a force acting in the direction of the axis of a shaft; as, the bearing that transmits the propelling force of a screw-propeller to the hull of a vessel.

Thuban. The star *a Draconis.*

Thule. The ancient name applied to the extreme north.

Thumb-cleat. A cleat used on a topsail-yard to prevent the turns of the reef-earing from slipping in on the yard.

Thumb-stall. A leather covering worn on the thumb by a captain of a gun to protect it from heat in serving the vent.

Thunder-squall. A squall accompanied by thunder and lightning.

Thunny. See TUNNY.

Thus, Very well Thus, or Dice. An old order to the helmsman, the ship being close-hauled, to steer as the ship heads. It is seldom used at the present day but by the oldest of quarter-masters.

Thwart. The seat in a boat upon which the rower sits.

Thwart-marks. Objects on shore near the coast, which being in line indicate the channel or the direction of shoals.

Thwart-ships. Athwart-ships (which see).

Tibric (*Eng.*). An old name for the coal-fish.

Ticket, Hospital. The document which accompanies a person in the naval service when sent to a naval hospital from a vessel, in which is stated the disease or injury under which the patient is suffering, and the evidence, if any, that said disease was contracted, or the injury received, in the line of duty. It also contains the descriptive list of the patient, and a list of clothing accompanying him. The ticket is signed by the medical officer of the vessel, and approved by the commanding officer of the vessel and the commandant of the station.

Tides (Sax. *tidan*, to happen; from *tid*, time). Semidiurnal oscillations of the ocean occasioned by the combined action of the sun and moon. The relative effects of these two bodies are directly as their mass, and inversely as the square of their distance, and the moon, although very small in comparison with the sun, is so much nearer that she exerts by far the greater influence on the phenomena of the tides.

The attraction of the moon on different parts of the earth is less as the distance is greater, and thus it influences the parts of the ocean nearest to her more powerfully than the body of the earth, and this again more powerfully than waters most remote. The particles of water under the moon have a tendency to leave the earth, but are retained by the superior attraction of the earth; again, the moon attracts the centre of gravity of the earth more powerfully than she attracts the particles of water in the hemisphere opposite to her, so that the earth has a tendency to leave these waters, which are retained, however, by the superior attraction of the earth. The effect of this difference of the attractions on the superficial water on opposite sides and on the central mass is two risings of the water, the one vertically below the moon, and the other diametrically opposite to this place. If the earth were entirely covered with an ocean, the waters would thus assume the form of an oblongated spheroid, having, if the earth had no rotation, its longer axis directed towards the moon and its shorter axis at right angles to that direction. As the moon in her apparent diurnal motion looks down successively upon each meridian, the protuberance of the ocean follows its motion from east to west; but by reason of the inertia of the water, this occurs at a meridian about 30° to the east of the moon. This great wave, following all the motions of the moon, is modified by the action of the sun. The sun raises a similar but much smaller wave, which tends to follow his motions, and which consequently at times combines with the lunar wave and at other times opposes it, according to the relative position of the two bodies. It must be particularly noted that the bodies do not draw after them the water first raised, but continually tend to raise that under them at the time. The tide is not a circulating *current*, but an immensely broad and excessively flat *wave*, which is propagated by the transits of the disturbing body. As this wave strikes the coasts the water gradually elevates itself to a certain height, then as gradually sinks to about the same extent below its mean level; and this oscillation is continued constantly, with certain variations in the height and in the times of attaining the maxima of elevation and depression. Considering the tides relatively to the whole earth and open seas, on the meridian

about 30° to the east of the moon there is high-water, on the west of this circle the tide is flowing, on the east it is ebbing, and on every part of the meridian at 90° distant it is low-water.

TIDES, NEAP- (Sax. *neafte*, scarcity). The smallest tides, being the result of the action of the moon and sun when they are conflicting. They take place after the moon is in quadratures, —*i.e.*, after the first and third quarter of the moon. The *smallest neap-tides* happen when the moon's and sun's attractions tend most to counteract each other, which will happen when the moon's action is the least possible and the sun's the greatest possible. This will evidently be—(1) When the moon is in apogee and the earth in perihelion at or near the same time; or, in other words, as the parallax of a body indicates its proximity to the earth, when the moon's parallax is the least, while the sun's is the greatest. (2) When the moon's declination and the latitude of the place are of different names, and the declination the greatest possible, at the same time that the sun's declination coincides or approximates to the latitude of the place, both being north or south; or, in other words, when the moon's altitude is the least possible and the sun's the greatest, the action being the more powerful in proportion as the body is more nearly vertical. The magnitude of the tide is also affected by strong winds and the state of the atmosphere. The action of the former is most conspicuous in rivers and narrow seas, and of the latter it has been observed that a rise in the barometer of an inch has been accompanied by a depression in the water of the tide of 12 or 14 inches.

TIDES, SPRING- (Sax. *springan*, to grow, bulge). The greatest tides being the result of the action of the moon and sun when they are co-operating, they take place after the moon is in syzygies,—*i.e.*, in conjunction or opposition, when it is new and full moon. The *greatest spring-tides* happen when the moon and sun are in such positions that their attractions produce the greatest effect upon the waters, especially when these positions are contemporaneous. These are—(1) When the moon is in perigee; when the earth is in perihelion. In other words (as the parallax of a body indicates its proximity to the earth), the effect of each body in raising the tide is greater as its parallax is greater. (2) When the moon's declination coincides with or approximates to the latitude of the place, both being north or south; when the sun's declination fulfills the like condition. In other words (as, generally speaking, the vertical action is the most powerful), the effect of the two bodies is greater as their altitudes are greater. The magnitude of the tide is also affected by strong winds and the state of the atmosphere; favorable winds and a low barometer are the meteorological conditions which augment the tides.

TIDE, SUPERIOR AND INFERIOR. The *superior tide* is that which takes place in the hemisphere which has the moon above the horizon; the *inferior tide* is that which happens simultaneously in the hemisphere which has the moon below the horizon.

TIDE-WAVE. The accumulation of the waters of the sea which is caused by the action of the moon, modified by that of the sun, changes its position through the day. The moon and sun in their diurnal revolutions continually and successively tend to raise the water beneath them at the time, and thus the alteration in the level of the sea is propagated from east to west, though there is no transference of the water itself except near the shore. Interruptions in the regular propagation of the tide-wave are caused by the depth of the ocean and the barriers presented by land stretching athwart its direction.

TIDE-CURRENT. The current in a channel caused by the alteration of the level of the water during the passage of the tide-wave. The tide-current does not generally change with the tide; thus, under certain circumstances, the current of the ebb continues to run for some hours after the flood-tide has made.

TIDE, RANGE OR HEIGHT OF. The difference between the level of high-water and that of low-water. Speaking of the earth at large, the range is greater in those latitudes over which the moon and sun pass vertically, being very small in high latitudes. In the open ocean the range is inconsiderable, and in inland seas almost insensible. It is most affected by local causes, as the shoaling of the water and the narrowing of the channel, especially if the channel opens in the direction of the tide-wave.

TIDE, RETARD OR AGE OF. The interval between the transit of the moon, at which a tide originates, and the appearance of the tide itself. It is found in general that any particular tide is not due to the moon's transit immediately preceding, but to a transit which has occurred some time before, and which is said therefore to correspond to it. The *retard of the tide* is thus distinguished from the *lunitidal interval*, which is the interval between the moon's transit and the high-water next following. The name *retard* is derived from the tide appearing to be "retarded" in following the moon in her diurnal course. The cause of the phenomenon may, however, be best understood by regarding the actual rotatory motion of the earth on its axis, instead of the apparent diurnal revolution of the moon in the heavens. The *momentum* of the water will cause a continuance of its rise long after it has passed under the excited cause. On the same principle, changes in the parallax and declination of the sun and moon produce their several effects on the time and height of the tide, not immediately, but after certain intervals.

TIDE, TIDE AND HALF-TIDE, TIDE AND QUARTER-TIDE. In the open sea high- and low-water succeed each other at intervals of about 6^h 12^m; such interval is designated "a tide." In channels where a tide-current is formed, when the stream continues to flow up for 3^h after it is high-water, it is said to make "a tide and half-tide"; if it continue to flow during 1^h 30^m after high-water, it is said to make "a tide and quarter-tide," and so on.

TIDE-DAY, PRIMING AND LAGGING. The tide-day is the interval between two successive arrivals at the same place of the same vertex of the tide-wave. It varies in length as the waves due to the separate action of the moon and sun approach to or recede from coincidence, the resultant maximum being at a point intermediate between them. The lengthening and shortening of the tide-day on its mean is called the *priming* and *lagging* of the tide.

TIDE ESTABLISHMENT OF THE PORT. The sun

and moon being in the same relative position, the time of high-water is different for different ports, owing to the inertia of the water and the obstructions it meets with from the friction of the sea-bed, and the narrowness, length, and direction of the channels along which the wave has to travel before reaching the port. It is of great maritime importance to be able to find the time of high-water for harbors and ports, and to this end a standard tide is fixed upon, indicated by a particular relative position of the moon and sun, from which the time of every tide may be deduced. This standard is called the *establishment of the port*, and is the time of high-water at full and change of the moon at the given port reckoned from apparent noon. It is the actual time of high-water when the moon passes the meridian at the same time as the sun, or the interval between the time of transit of the moon and the time of high-water on full or change days. It may be determined roughly by observation on the day of full or change, and is, in this case, distinguished by Whewell as the *vulgar establishment of the port.* The *corrected establishment of the port* is the interval between the time of the moon's transit and the time of the tide not *on* the day of syzygy, but *corresponding to* the day of syzygy. It may be determined by observing the intervals of the times of the moon's transit and the times of tide every day for a semi-lunation, and taking the mean of these. If we know by how much the transit of the moon to which the tide corresponds is antecedent to the transit next preceding the tide, the corrected establishment may be obtained from one observation of any tide. The establishment of the port is spoken of by Robinson as "the time of the syzygie high-water for the given port," which may be abbreviated into *syzygy tide;* similarly, it has been called the *change tide.*

Tie. That part of the purchase for hoisting a topsail-yard which is attached to the yard and passes through the sheave-hole in the mast, or the tie-block at the mast-head. *Tie of a cartridge*, the end of the cylinder secured by a woolen thrum after the cartridge is filled.

Tie-for-tie. A former expression indicative of exchange of courtesy and good-will, handed down from the days when cues were worn, and tying required to be performed by another.

Tier. A row or layer; as, the upper or lower tier of casks. The *cable-tier* is that part of a vessel's hold where the hawsers or hemp-cables are stowed.

TIERER. A man stationed in the chain-locker to stow the chain; but formerly, one stationed in the cable-tier for the stowing of hemp-cables,—hence the name.

TIER-SHOT. Grape-shot in which the several layers or tiers are secured by parallel iron plates.

Tierce. A cask of the capacity of 42 wine gallons. Also, a measure of the same amount. A cask used in packing salt provisions, containing 336 pounds.

Tie-ties. Stops of small cord, sometimes used in securing a hammock, in place of a hammock-lashing.

Tight. Free from leaks; applied either to a cask which retains a liquid or to a ship which excludes it. *Taut* is used in place of *tight* when speaking of a rope upon which there is a strain.

Tiller. An iron or wooden bar fitting into the socket near the rudder-head, which forms the lever by which the rudder is moved.

TILLER-HEAD. The end of the tiller farthest from the rudder.

TILLER-ROPES, or WHEEL-ROPES. Ropes which connect the tiller with the wheel. They are usually made of hide. Small chains or wire-ropes are sometimes used for that purpose in merchant steamers.

TILLER-SWEEP. See SWEEP.

Tilt (*Eng.*). A small awning sometimes used to protect the stern of a boat.

TILT-BOAT (*Eng.*). A boat covered with canvas, in which articles can be protected from the weather.

Timber. A name given to any of the pieces of timber which compose the frame of a ship; as, floor-timbers, futtock-timbers, top timbers, etc.

TIMBER AND ROOM. The space from the centre to the centre of the frames.

TIMBER-HEADS. Projecting timbers for belaying towing-lines, etc.

TIMBER-HITCH. A hitch made by passing the end of a rope around an object, then over and under the standing part, and securing the end from slipping by taking two or three turns around its own part.

Time. A definite portion of duration. It is marked, in a general manner, by the recurrence of striking natural phenomena, such as the alternations of light and darkness, and the succession of the seasons. Thus the two natural measures of time are the *day* or period of the earth's rotation on her axis, and the *year* or period of the earth's revolution in her orbit. See CALENDAR.

Time, in the abstract, is reckoned from an epoch (or initial instant) independent of local situation, —such is that known among astronomers as *equinoctial time*, which is the same for all the inhabitants of the earth. *Local time* is reckoned at each particular place from an epoch determined by local convenience, such as the transit of the sun's centre over the meridian of the place; what is called *Greenwich time* and *ship-time* are both examples of local time.

The day depends upon the rotation of the earth on her axis, but this is indicated to a spectator on the surface only by the apparent revolution of the celestial sphere in the opposite direction. Diurnal time is, therefore, defined by the motion of some chosen point in the heavens as it appears to revolve from east to west, and is measured by *the angle at the pole of the heavens between the celestial meridian and the hour-circle passing through the point of definition, reckoning westward.* Thus we have *sidereal time*, *apparent solar time*, and *mean solar time*, according as the point of definition is the first point of Aries, the actual sun, or the mean sun.

TIME AZIMUTH. An azimuth determined by calculation from the latitude, the declination, and the hour-angle. An *altitude azimuth* is an azimuth determined by calculation from the latitude, the declination, and the altitude.

TIME-BALL. A ball attached to a mast or staff, placed in a position where it can be easily observed. The ball is dropped on its staff at a certain instant of mean time, usually at meridian, and affords an opportunity for correcting chronometers.

TIME-FUZE. A fuze so constructed as to burn

a certain number of seconds after ignition by the flame from the charge, exploding the shell at the end of that time.

TIME-KEEPER. An instrument for the measuring of time.

TIME, SHIP-. The mean solar time at the place where a ship happens to be, as contrasted with *Greenwich mean time.*

TIME-SIGHT. The name usually applied to an observation of the altitude of a heavenly body for the purpose of obtaining the mean time of observation, from which the longitude is deduced.

Timenoguy. A rope stretched from one place to another to prevent gear from becoming foul. That most commonly used extends from the fore rigging to the anchor-stock to keep the fore tack and sheet clear of the anchor-stock in tacking. The pendant which extends from the mizzen-top to the main-brace block as a support to the latter is sometimes called by the same name.

Timonogy. A gauge or tell-tale formerly used in large ships, by which the position of the tiller could at all times be known.

Tindal. A Lascar boatswain's mate.

Tinker (*Eng.*). A small mortar which was formerly used in ships of war. Also, a mackerel of small size; also called skate.

Tinkerman (*Eng.*). A name formerly applied to fishermen of the Thames who took fish with nets, contrary to law.

Tin-potter. A galley skulker.

Tip All Nines (*Eng.*). To founder; the result of carrying too much sail.

Tippet (*Eng.*). A snood on a fishing-line.

Tip the Grampus. To duck a look-out for being asleep.

T-iron. Bar-iron having a cross-section of the form of the letter T.

Titivate. To clean and put to rights.

T-joint. In pipe-fitting, a joint by which three pieces of pipe are connected in the form of the letter T; two pieces being continued on the same axis, and the third branching at right angles therefrom.

Toad-fish. The *Lophius piscatorius*, or fishing-frog.

Tobacco-chart (*Eng.*). The name formerly given to a worthless kind of chart sold by ship-chandlers.

Tod-boat. A Dutch fishing-boat.

Toddy. The juice extracted from the palm and sometimes called palm-wine. Also, a mixture of spirits, sugar, and water.

Toe a Seam. To stand on deck without moving,—a punishment sometimes given for minor offenses.

Toggle. A piece of wood varying in size and strength, used for connecting two ropes in place of a hook. The toggle being fixed to the end of one rope is passed into the eye made in another, like a button. By this means bowlines are fastened to their bridles, and buntlines to the foot of a topsail or course. Toggles are frequently fastened to the lower and topsail braces to prevent them from unreeving from the brace-block on the yard-arm in case of injury to the brace. A heavy toggle is used by whalers for attaching the blubber to the lower purchase-block in "cutting in," it being more easily handled than a hook.

TOGGLE-BOLT. A bolt used in confining an iron band or strap in its place; as, the band by which a boat's mast is secured to a thwart, or a flag-staff to the stern of a vessel.

Togs. An old name for clothes among sailors. *Sunday togs* are best clothes, and *long togs* are those worn by people on shore. An officer *togged to the nines* is in full dress.

Toke. A drink made from honey on the island of Madagascar.

Toko for Yam. An expression used by the negroes of the West India Islands, meaning to cry out before being hurt.

Tom Astoner. A gay, dashing fellow.

Tomcod. The fish *Morrhua pruinosa*, which is found on the coast of America at the time of frosts; hence called *frost-fish.*

Tom Cox's Traverse signifies the efforts made by a skulker to avoid work. It has been described by "Up one hatchway and down another;" also, "Three turns around the long-boat and a pull at the scuttle." But the traverse is not limited to these descriptions.

Tomnoddy, or Tomnorry. A fish; the *Fratercula artica.*

Tom Pepper. The name for a liar.

Tompion. A wooden plug placed in the muzzle of a gun to keep out water and dust.

Tom-tom. A rude drum used by the natives in tropical countries.

Ton. 20 hundred-weight, or 2240 pounds. A short ton of 2000 pounds is frequently used. A ton in space is estimated at about 40 cubic feet. *Ton for ton and man for man*, an expression meaning that all the vessels of a fleet should share, according to tonnage and number of crew, in the prizes taken.

Tonee. A canoe formerly used on the coast of Malabar.

Tongs, Shot-. An iron instrument used in hoisting or lowering shot from one deck to another.

Tongue. A low point of land. Also, a mass of ice projecting under water from an iceberg. The name is also applied to the long tapered end of a piece of timber which is joined to another piece by scarfing. *Tongue of a bevel*, the movable part of a beveling instrument.

Tonnage. The contents or burden of a ship in tons, which is commonly calculated by builders and merchants by a curious rule, given hereafter, producing what is called the builder's tonnage. The real burden a ship is to carry when brought down to the load water-line can be ascertained by the use of one of the several rules in use for finding the displacement of a ship and the making of a scale of displacement therefrom.

The rule established by law in the United States under act of 1799, and which continued in force until superseded by that given in the law of May 6, 1864, provided that from the extreme length of the vessel there should be deducted three-fifths of the breadth; the remainder was multiplied by the breadth and the product by the depth, which in the case of a double-decked vessel was arbitrarily assumed as being equal to one-half the breadth; the latter product was then divided by 95, and the quotient was taken as the legal tonnage on which tonnage dues were to be paid. It was thus made the interest of owners to build excessively deep ships, the law in this way discriminating in favor of

clumsy, slow, and inefficient ships, and discouraging attempts at improvements in model.

By the act of May 6, 1864, vessels are divided into six classes according to length, those in each class being divided into a certain number of equal parts or transverse sections, to which different values are assigned in computing the total tonnage of the vessel; the actual depths between decks are measured and taken as factors, and any closed-in space on or above the upper deck and capable of receiving cargo, etc., is included in the measurement.

The dimensions are all taken in feet and decimals of a foot, and the number 100 is used as the final divisor for ascertaining the capacity of the ship in tons, instead of 95, as in the old law.

Class 1. Vessels under 50 feet long, divided into 6 equal parts.

Class 2. Vessels 50 to 100 feet long, divided into 8 equal parts.

Class 3. Vessels 100 to 150 feet long, divided into 10 equal parts.

Class 4. Vessels 150 to 200 feet long, divided into 12 equal parts.

Class 5. Vessels 200 to 250 feet long, divided into 14 equal parts.

Class 6. Vessels over 250 feet long, divided into 16 equal parts.

The details for making the measurements and calculations are too long to be inserted here, but may be found in "Revised Statutes of the United States," Section 4153.

The rule adopted in England by the Merchant Shipping Act of 1854 is essentially the same as that established in this country: the measurements are made in feet and decimals, and the principles of calculation are identical. Vessels are divided as follows:

Not exceeding 50 feet in length, into 4 parts.
Not exceeding 120 feet in length, into 6 parts.
Not exceeding 180 feet in length, into 8 parts.
Not exceeding 225 feet in length, into 10 parts.
Over 225 feet in length, into 12 parts.

In steam-vessels the length, breadth, and height of the engine-room are multiplied together, the product divided by 100, and the result deducted from the gross tonnage. The space occupied by the propeller-shaft is considered as a part of the engine-room.

It would seem that the American method, employing, as it does, a greater number of divisions for the same length, should be slightly more accurate than the English, or afford at least, on the average, a somewhat nearer approximation to the true capacity of a vessel; either, however, may be relied on generally as coming within 4 or 5 per cent. of the truth. This difference may, in extreme cases, amount to 10 or 12 per cent., a trifling error as compared with those incident to the old system.

The ton measurement upon which freight is charged is calculated at 40 cubic feet; the difference between that and the ton of 100 cubic feet, or that of the register, represents the dead weight or displacement of the ship when light, or 60 per cent. of the whole, 40 per cent. only being available flotative power for cargo.

Top. A platform of semicircular form resting upon the trestle-trees of the lower mast of a square-rigged vessel. It gives spread to the topmast rigging, which is set up to the rim of the top. It also serves as a place for sharp-shooters during an engagement, and in a large vessel is of sufficient size for the use of a howitzer. It is of use as a landing-place from which the light-yard men start in loosing or furling, as a place where topgallant and royal studding-sails are kept at sea, and from which they are set, and where men are stationed to set or take in royals, and light studding-sails when the gear is brought into the top instead of to the deck. The top is supported on the under side by the futtock-shrouds, which extend from the rim on each side to a band on the lower-mast below the cheeks. The breadth of a main-top is equal to one-half the molded breadth of beam, and its length is five-eighths of its breadth. The size of a fore-top is nine-tenths that of the main-top, and the size of a mizzen-top is five-sevenths that of the main-top. *To top a boom*, to raise the outer end by means of the topping-lift. *To top the glim*, to snuff a candle. *To top the officer*, to take upon one's self airs of superiority.

TOP-ARMINGS. Hammocks stowed in the tops to serve as a protection for small-arm men during action.

TOP-BLOCK. A heavy iron-strapped block through which the top-pendant reeves in sending a topmast up or down.

TOP-BURTON. See TACKLES.

TOP-CASTLE. A protected place at the mast-heads of ships built in the early days of the English navy, from which darts and arrows could be thrown upon the enemy's deck.

TOP-CHAIN. A chain used as an additional support for a topsail-yard in case of injury, during action, to the ropes by which it is held in position.

TOP-LIGHT. A large lantern carried in the mizzen-top of a flag-ship at night.

TOP-LINING. A lining-cloth sewed to the after side of a topsail to protect it from chafing against the rim of the top.

TOPMAN. A man stationed for duty in one of the tops.

TOP-MAUL. A heavy hammer, resembling a sledge.

TOP-NETTING. A netting fastened to the rail and stanchions at the after rim of a top.

TOP-PENDANT. A large rope used in sending a topmast up or down. It passes through the top-block at the lower-mast head, then through the sheave-hole near the heel of the topmast, and secures at the head of the lower-mast. It is of sufficient length to allow the heel of the topmast to reach the deck.

TOP-RAIL. A light iron railing, placed at the after rim of a top.

TOP-RIM. The circular sweep which forms the edge of a top.

TOP-ROPE. See TOP-PENDANT.

TOP-SWIVEL. A small gun formerly used in a ship's top.

TOP-TACKLE. See TACKLE.

Top-and-butt. A method of working planking, causing every other seam to present a fair edge.

Tope. A species of shark. Also, the name of a small Chinese junk.

Topgallant. The name applied to the mast, sail, yard, and the ropes belonging to each which are next above the topmast and topsail. It is also applied to portions of the deck or rail raised above the rest.

Topgallant-forecastle. A short deck in the bow of a vessel above the spar deck. In ships of war it is of sufficient size for the working of a gun as large as a 60-pounder, and a part of the crew can be berthed underneath. The cables are also worked under the topgallant-forecastle in sloops-of-war and merchant vessels.

Topgallant-mast. The mast above the topmast. The topgallant-mast and royal-mast are usually made from a single spar.

Topgallant-rail, or Bulwarks. A light rail or bulwarks built upon the main bulwarks of a vessel.

Topgallant-sail. The sail next above a topsail.

Topgallant-yard. See Yard.

Top-hamper. Unnecessary spars and rigging kept aloft.

Top-knot. A species of flat-fish of the genus *Rhombus* (*R. punctatus*).

Topmast. The mast next above the lower-mast. See Masts.

Topsail. See Sails.

Topsail Schooner. A schooner which carries a square topsail on her fore-topmast. When sailing before the wind a square-sail can then be set upon the lower yard. A schooner which has a square topsail upon both fore- and main-topmasts is called a *two-topsail schooner*.

Topsail-sheet Bitt. A bitt or timber-head near the lower-mast, through which a topsail-sheet is rove, and to which it is belayed.

Topsail-yard. See Yard.

Top-sawyer. One who takes the leading part in any work.

Top-sides. The upper part of the ship, including all above the water-line.

Top-side Lines. The general outlines of the top-sides, either forward and aft, or vertically.

Top-timbers. The uppermost timbers composing the frame of a ship.

Top-timber Line, or Top-breadth. The curve limiting the height of the sheer at the head of the top-timbers.

Tor (Ang.-Sax. *torr*). A high peak or rock.

Tormenter. A large iron fork with two prongs, used by the ship's cook in taking meat from the coppers.

Tornado. A tempest distinguished by its revolving as well as progressive motion. See Storm, Revolving.

Torpedo. A species of ray (*Torpedo vulgaris*) having electric power. It is found in the Mediterranean and Atlantic. It is also called *cramp-fish*.

Torpedo. This term is properly applied to a torpedo used in attack only, those used for defensive warfare being called *submarine mines*.

Capt. David Bushnell, of Connecticut, was the originator of the idea of torpedo warfare; but Robert Fulton first called a magazine of powder intended for use under water a torpedo. Bushnell carried on his experiments before the Revolution, and made some unsuccessful attempts during that war to blow up the enemy's vessels. Fulton's experiments, carried on abroad and afterwards in the United States, came to an end previous to the war of 1812. The non-success of torpedoes during that war, and the general feeling against this mode of warfare, as inhuman and barbarous, caused all experiments to cease for many years. Both these inventors thought it necessary to construct and use submarine boats for this kind of warfare. The difficulties met with in the attempted solution of this problem, together with the want of steam as a motive-power, and the necessity of using clock-work to explode their torpedoes, caused almost all their efforts to prove abortive. No further experiments of importance with movable torpedoes for offensive warfare were made until the civil war of 1861–65. During the summer of 1863 they were first brought into general use. The torpedoes employed by the rebels were of various forms and sizes. They were usually made of stout copper, although torpedoes made of barrels and other vessels were occasionally extemporized; they contained from 50 to 150 pounds of powder, according to circumstances. Every description of vessel in their service was fitted with torpedoes, generally a spar attached to the vessel by a goose-neck and controlled by guys and tackles was used. They also constructed boats especially for torpedo warfare; these boats were generally known as davids, from their small size. The fuzes fitted to the torpedoes were generally of the percussion type, so as to explode on contact.

The complete destruction of the sloop-of-war "Housatonic," February, 1864, was by a torpedo fitted with such a fuze, carried by a submarine boat. The "Minnesota" was considerably damaged by a torpedo containing 53 pounds of powder carried on the end of a spar from an ordinary steam-launch. The various attacks made at other times as a rule did but little damage. The destruction of the "Albemarle" by Lieut. Cushing was accomplished by a torpedo consisting of a copper cylindrical case filled with powder, through the centre of which there was a hollow tube; at the bottom of this tube was a large fulminate cap; a small-sized grape-shot was held at the upper end of this tube by a pin.

The torpedo was exploded by pulling a line connected to the pin, which being withdrawn allowed the grape-shot to run down the hollow tube inside the torpedo and explode the fulminate cap.

The rebels were very successful in blowing up vessels by torpedoes planted in their rivers and harbors, but, according to the division already spoken of, these come under the title *submarine mines*.

Drifting torpedoes were also used, but with indifferent success, on account of their primitive form.

They were but little better than those used by Bushnell, at Philadelphia, in 1777, which caused the panic and engagement known as "the Battle of the Kegs." This kind of torpedo might be used with advantage against pontoon bridges, booms, etc., and several kinds have been devised for this purpose. In fact, the first torpedoes used were of this nature. They are frequently fired by the revolution of a paddle-wheel, or other action of the current upon the torpedo after it has brought up against the obstruction; the current having no effect while the torpedo is drifting with it.

Another kind of torpedo is known as the Otter, or towing-torpedo. These can be fired either by contact or electricity. Considerable interest was manifested a few years since in the "Harvey towing-torpedo." This torpedo was towed on the quarter of the attacking vessel,

which by passing or other means was supposed to bring the torpedo in contact with the vessel to be destroyed. While in theory it was rather plausible, in practice it was not successful.

There are some other types of towing-torpedoes, but none are much superior to the Harvey.

Those torpedoes which possess within themselves the power to move through the water are sometimes called locomotive-torpedoes; to this class belong the Whitehead fish-torpedo, the Lay torpedo, and Rocket torpedoes.

The Whitehead torpedo is cigar-shaped, being largest at the middle and tapering to each end. It is divided into three compartments; the forward compartment carries the charge, the middle section carries the adjustment mechanism, in which lies the secret of the invention, and the after part contains the air- and engine-chamber. It is driven by compressed air, the engines being able to exert a force of 40 indicated horse-power, and weighs but 35 pounds. The torpedoes vary in size from 14 to 19 feet in length, and from 14 to 16 inches in diameter, and have a speed varying from 10 to 20 knots an hour for the distance of 1000 yards. It is fired mechanically, either upon contact or after having run to any desired distance. It can be adjusted so as to run any depth from surface from 5 to 15 feet. In still water without currents it will travel in a straight line. It can be adjusted to stop after having run any distance up to its extreme range, and after stopping to sink, float, or explode. The torpedo can be projected from tubes under water either right ahead or on the broadside. It can also be projected from the surface. The first time this torpedo was used in actual service was in the engagement between the "Shah" and "Huascar," when it completely failed; it was said the distance was too great. The second attempt to use it was by the Russians against the Turks, December, 1877. Two were fired, both missed, and went ashore on the beach. The third and last time by the Russians, January, 1878. Their torpedo-boats undertook to enter the harbor of Batoum to attack the Turkish fleet, but met a Turkish revenue-steamer, at which they discharged their torpedoes and destroyed her. The alarm given caused this to end the attack. The results accomplished so far are not at all commensurate with the money and trouble expended on this torpedo.

The Lay torpedo somewhat resembles the Whitehead torpedo in its general design. Ammoniacal gas supplies the motive-power. The torpedo is connected with the ship or shore by an insulated wire, and carries above-water some visible object. The wire is carried on a reel in the torpedo, and pays out as the torpedo runs its course. By it the torpedo may be started, stopped, steered, fired, sunk, raised, etc. It has been said of this invention that it can do everything but talk. It can be discharged from ships or from the shore, but it is doubtful if such a torpedo would prove manageable in a sea-fight. They are besides very expensive, and the successful handling of them requires a person of experience and ability. However, it would appear to have advantages over the Whitehead torpedo, which is sure to miss the object aimed at when influenced by tides or currents.

Finally, there is the spar-torpedo, which remains a favorite with many of the officers of our navy. This is a great recommendation in its favor, as torpedo warfare originated and has been chiefly developed in this country. Nearly every success with offensive torpedoes has been made by a torpedo carried on the end of a spar projecting from a boat or vessel. They should explode on contact, and by electricity at will. This makes explosion a certainty. Had it been necessary for the late Commander Cushing to explode the torpedo used by him with a Farmer machine, it is probable he would not have destroyed the "Albemarle." The ordinary service fuze is exploded by the electricity heating a fine platinum thread, which makes a bridge within the fuze itself. These fuzes are made very perfectly at the Torpedo Station.

In case of war, the small steam-tugs, yachts, etc., in our harbors would make good torpedo-boats. They could be quickly and cheaply fitted for service. Doubtless it would be better to have a large number of small, very fast boats, especially designed for this purpose, on hand ready for an emergency. In an attack it is probable that many of them would be destroyed, but a successful explosion by one would destroy any ironclad.

The torpedoes used on the "Alarm" are of a shape not unlike an ordinary elongated projectile, having the outboard end hemispherical. Those for the bow spar are 4½ feet long and 1 foot in diameter, and hold 100 pounds of powder. Those for the side spars are not so long. The end of the spar enters the torpedo-shell for about a foot, there is a space then of about 6 inches for water to act as a cushioning, then there is a diaphragm with an opening in centre, for the water-tight fitting fuze. The wires are brought up within the spar, and are connected with the key-boards. The torpedoes are fired by a Farmer dynamo-electric machine run by a small steam-engine. The spars run out under water by steam-power, and work satisfactorily. The torpedoes are of the same diameter as the spar, and are put on before the spar is run out. See SUBMARINE MINES.—*R. M. G. Brown, Lieutenant U.S.N.*

Torpedo-boat. The torpedo-boat proper is a very light fast boat, carrying no stores and only a few men. They are only used for harbor-work, unless carried at the davits of larger vessels and lowered in action at sea. The term, however, has frequently been applied in a much more general sense, so as to include vessels of several hundred tons displacement, and also such torpedoes as the Lay torpedo, which is managed by electricity conveyed through an insulated wire from the shore or ship.

David Bushnell, of Connecticut, was the first to call attention to torpedoes and torpedo-boats. He designed a submarine torpedo-boat during the latter part of the last century. His boat carried but one man, and held enough air to allow him to remain below the surface for half an hour. By an ingenious arrangement of oars the operator was enabled to propel and steer his boat. A magazine containing a clock-work was carried on the boat, and by a simple device the operator was to fasten a wood screw into the bottom of the enemy's vessel, which screw was connected by a line to the magazine of powder. The screw having been fastened into the vessel's bottom, the magazine and clock-work were to be detached from the boat and left hanging to the screw,

after which the boat was immediately to retreat. He made various unsuccessful attempts to destroy the enemy's vessels during the Revolution. Washington furnished him with means to carry on his operations, as also did the province of Connecticut. It is no wonder he failed, as the experience of a century has not produced a successful submarine torpedo-boat.

Robert Fulton next became enthusiastic on the subject; he also tried to introduce a submarine boat for torpedo warfare, but after many attempts in France, England, and the United States, was finally forced to give up the plan. He, however, met with some success in blowing up vessels with submarine mines. His experiments came to an end just previous to the war of 1812. During that war some ineffectual attempts by different parties to destroy British vessels further lessened the low estimation held of this method of warfare. Although Col. Samuel Colt successfully experimented with submarine mines, fired by electricity, about the year 1840, no advancement in the science of offensive torpedo warfare was made until the civil war. The rebels having been somewhat successful with submarine mines in 1862, commenced offensive operations the following year with torpedo-boats,—in fact, all kind of vessels were fitted with torpedoes. Several boats were constructed at Charleston, S. C. As a rule they were cigar-shaped, nearly submerged, and carried only 4 or 5 men. They could steam 6 or 7 knots, and were intended for use in smooth water only. One of these boats made an unsuccessful attempt on the ironclad "New Ironsides" in October, 1863. In the following February, in the same harbor, the sloop-of-war "Housatonic" was destroyed by a submarine boat. This boat, however, carried 9 men, and was propelled by a screw worked by 8 of them. She could be submerged at pleasure to any desired depth, or could be propelled on the surface. She was built of boiler-iron, and was 35 feet long. Her greatest speed was about 4 knots an hour in smooth water. She was carried down with the sloop, but was raised after the war, the 9 men being found in her. Several unsuccessful attempts were soon after made upon other vessels of the blockading fleet. Torpedo-boats obtained such a reputation that they were greatly dreaded. An attack upon the flag-ship "Minnesota," at Newport News, April 9, 1864, did considerable damage, but did not sink the frigate. The boat used on this occasion was an ordinary steam-launch decked over with boiler-iron, and filled with a spar-torpedo carrying 53 pounds of powder. The destruction of the "Albemarle" by Lieut. Cushing, in October, 1864, was the only occasion during the war in which a torpedo-boat was successfully used by the Federal navy. This boat was designed by Chief Engineer Wood, U. S. navy, and Mr. J. L. Lay. It was an ordinary steam-launch, armed with a torpedo. The torpedo was rigged out ahead of the launch on the end of a spar, and was fired by pulling a laniard, which allowed a small grape-shot to roll down against a fulminate cap. The same parties afterwards designed the "Spuyten Dyvil," a very complete torpedo-boat of 200 tons displacement, but the termination of the war prevented a thorough test of efficiency.

In England, of late years, much attention has been paid to the construction of very fast light boats for torpedo warfare. Messrs. Thornycroft & Co. and Messrs. Yarrow & Co. are the best-known firms engaged in this business. The boats they construct are generally of steel, covered over with a light deck. They, generally speaking, are from 50 feet to 90 feet in length. Some are intended to be carried at sea on large vessels, being hoisted in and out as necessary. Messrs. Thornycroft have also an arrangement by which these boats can carry and use the Whitehead fish-torpedo. The spar-torpedo has been used very successfully with these boats.

Messrs. Herreshoff, of Rhode Island, have constructed a large number of very light fast boats fitted with the Herreshoff boilers. The propeller is under the centre of the boat, and they are fitted with a large balance-rudder. They are constructed for use on smooth water only.

Capt. Ericsson has recently constructed a torpedo-boat, the "Destroyer"; she is 130 feet long, 11 feet deep, and 12 feet beam. Her speed, though good, has not as yet been entirely satisfactory. The torpedoes were to be discharged from a tube under water, by compressed air or other agent, but as yet the plan has not proved a practical success.

The "Alarm," a torpedo-ram, was built from plans designed by Admiral Porter, U.S.N. Her total length, including a ram 30 feet long, is 173 feet, beam 28, and 13 feet depth of hold below spar-deck. She is built on the transverse bracket system, with a double bottom. She has a tonnage of 311 tons within the inner skin, and a displacement of 720 tons. She was originally fitted with the Fowler wheel, an invention which enabled the whole energy of the main or driving-engines to be instantly diverted for steering purposes, and then instantly restored for driving purposes. This handiness was, however, at the expense of speed. She is now being fitted with the Mallory propeller, by which it is hoped she will have the same handiness and, at the same time, the speed of the ordinary propeller. She is protected by 4½ inches of armor on the bows, and designed to fight bows-on at all times. This thickness of armor is thought to be sufficient to cause the heaviest projectile to glance when fired from directly ahead.

There is a 15-inch smooth-bore gun on the bows, and she carries a number of Gatling-guns on the rail. The system of torpedo-spars run out under water by steam-power, one ahead 30 feet, and one on each side 18 feet. The torpedoes are fitted to the end of the spars before running them out. They are fired by electricity, as is also the gun. Should the Mallory propeller prove successful, she will be one of the most formidable vessels in the world, and of a type very suitable for the protection of our coast.

The "Polyphemus," now under construction in England, bears a considerable resemblance to the "Alarm," being a torpedo-ram, but carrying no gun. She is to have a turtle-back armor, and is to be fitted for discharging Whitehead torpedoes. Length, 240 feet; beam, 40 feet; and draft, 20 feet. A speed of 17 knots over the measured mile is anticipated.

The efficiency of the Whitehead torpedo for actual war is by no means settled: it has failed twice to where it has succeeded once. Nearly every success with offensive torpedoes has been accomplished by the spar-torpedo.

The great expense and delicate handling required in manipulating the Lay torpedo will probably prevent its general use; yet, if properly handled, it may prove to be extremely valuable for harbor use. The ease with which it can be turned, stopped, fired, etc., is very wonderful.

As submarine boats have apparently been given up, it is probable that for harbor defense there is nothing cheaper and surer than light boats with the spar-torpedo. These would also be useful at sea if carried by large vessels and lowered in action.

For coast defense, torpedo-rams of the general principle of the "Alarm" would seem to be the best. When torpedoes can be discharged from guns or tubes under water, torpedo-ships for cruising upon the high seas will doubtless come into favor.—*R. M. G. Brown, Lieutenant U.S.N.*

Torpedo Station. The civil war first brought torpedo warfare into prominent notice. In order that the naval service should be thoroughly informed on this subject, Admiral Porter conceived the idea of establishing a torpedo school, where the officers of the service could be instructed in the manufacture and use of torpedoes. In this he was ably seconded by the chief of the Bureau of Ordnance, Rear-Admiral Case, whose zeal and ability brought the torpedo school up to its present standard. Commander Matthews was selected as a suitable officer to found the institution. Accordingly, he was ordered on June 9, 1869, to duty under the Bureau of Ordnance as instructor of the torpedo corps of the navy. During the following summer he was ordered to select a suitable place for the headquarters of the torpedo corps. As it would have required an act of Congress and the consent of the Legislature of the State to obtain possession of any land for this purpose, it was desirable to find a suitable site upon land already owned by the general government. It was finally resolved to establish the station on Goat Island, in the harbor of Newport, R. I., that island being transferred, in accordance with arrangements made by Rear-Admiral Case, from the War to the Navy Department. In the following September Commander Matthews took possession, and commenced building the necessary shops, etc. An old frame house was converted into a temporary machine-shop, and a laboratory and magazine were erected. During the winter the old barracks, now the commanding officer's quarters, were converted into offices and a manufacturing laboratory. In the spring of 1870 the "Nina" was ordered to the station, the crew being for general use connected with the station. Several officers had by this time been ordered to duty under Commander Matthews, and a competent chemist was appointed to take charge of the laboratory. During the summer of 1870 the north end of the old barracks was fitted up for quarters for the commanding officer, who soon after took up his residence on the island, about the same time the nitroglycerine manufactory was established. During the summer of 1871 three cottages were built for officers' quarters, and the following summer two more were constructed, completing the present row. In the fall of 1872 the machine-shop was commenced. This important building was finished the following spring. Professor Farmer, an experienced electrician, was secured as a permanent instructor in 1872. The first class of officers ordered for instruction reported November 1, 1870, and consisted of 19 members. They remained until April, 1871.

The difficulty of getting officers of rank and experience to again resume the tasks and recitations of their school-days was very considerable, but the zeal and patience of the commanding officer was finally rewarded by success. A second class was ordered June 1, and remained until January 13, 1872. The third class succeeding this one remained until August 1, 1872. It was now found that the instructors needed more rest, and accordingly the class ordered September 1 remained until the following July (1873), when there was a vacation until September 1, at which time the succeeding class reported. Considerable trouble was caused by the dislike of the officers to the manual labor necessary in fitting, laying out, and firing the torpedoes, as no men were allowed to assist in this work. However, this also was overcome, and officers of rank could be seen daily with aprons on, experimenting with chemicals, or carrying powder and fitting torpedoes. All the work was done by the officers themselves, even to pulling the boats and transporting the torpedoes.

Commander Matthews was relieved by Capt. Simpson on July 1, 1873. During the summer of 1874 a new building for electrical purposes was erected, a change was also made in regard to the time the classes should attend. The officers that year were ordered to report July 1, and were at the school only four months, the practical part of fitting and firing the torpedoes being particularly taught. This has been the custom since that time, but the course of study has been much elaborated.

Capt. Simpson was relieved in June, 1875, by Capt. K. R. Breese, who was relieved by Capt. Ramsey, the present commanding officer, in 1878.

The course of instruction embraces chemistry, electricity, and physics, with an additional course of instruction in the practical manufacture of explosives, including nitro-glycerine, dynamite, gun-cotton, and various fulminates used in torpedo warfare. Instruction is given in the practical making of fuzes and the testing and firing of them. Each officer is obliged to fit torpedoes, plant and fire them. At the end of every term a board of experienced officers is ordered to witness the examination of the officers under instruction, and report to the Department the condition of the institution.

The torpedo station undoubtedly accomplishes the object desired by its founder, and the service and country are indebted to the officers who by their zeal and energy made the experiment a success.—*R. M. G. Brown, Lieutenant U.S.N.*

Torquay, a favorite watering-place of England, Devon County, is picturesquely seated on the shore of a cove of Torbay. It consists chiefly of handsome villas and terraces. It has a good harbor, some timber trade, a share in the Newfoundland fishery, regular steam communication with Portsmouth and Plymouth, and well-supplied markets. Pop. 21,657.

Torrent. A stream of water in mountainous districts, swollen by rains or melting snow.

Torse. A coarse kind of hemp used in the manufacture of an inferior quality of cordage.

Torsk. See Tusk.

Tort. A term in law for a wrong or injury.

Tortue de Mer (*Fr.*). A sea-turtle. The term is also applied to a French store-ship or transport.

Tosh (*Eng.*). A cant word, meaning to steal copper from a vessel's bottom.

Toss the Oars. To take the oars from the rowlocks and bring them to a perpendicular position, with the ends resting in the bottom of the boat. Oars are tossed in this manner as a salute from a boat containing an officer below the rank of a commanding officer, to a boat containing an admiral, vice-admiral, rear-admiral, or commodore. When a boat goes alongside a vessel or a wharf, the oars are tossed and laid into the boat at the order given by the stroke-oarsman.

Toss up the Bunt. To roll the bunt of a sail on to the top of the yard.

Tot. A drinking-cup holding a little less than half a pint, in which the spirit ration was served out. The difference between this measure and the half-pint was the share of the mess-cook.

Toucan. See Constellation.

Touch. The broadest part of a plank worked top-and-butt, which place is 6 feet from the butt end. The sudden angles in the stern timbers. *Touch-and-go*, a term descriptive of any narrow escape. *Touch-and-take*, an expression of Nelson's applied to a vessel about to engage the enemy. *To touch at*, to stop at a port for a short time, being on a passage between two other ports. *To touch the sails*, to cause the weather leeches of sails to shake by sailing too near the wind. *To touch up a sail*, to mend the furl of a sail, or make it more snug on the yard.

Touch-box. The box in which lighted tinder was formerly carried by soldiers armed with match-locks.

Touch-hole. A common name given to the vent of a gun.

Touch-wood. Decayed wood or punk, used for producing fire from a spark.

Toulon. A seaport city and naval station of France, admirably situated at the bottom of a deep double bay formed by the Mediterranean. Lat. 43° 7′ N.; lon. 5° 56′ E. In front of the bay is a projecting tongue of land, which nearly closes its entrance, and along it, as well as the adjacent points, numerous forts have been erected. In like manner, on the land side, the fortifications are of the most complete description. The arsenal and other marine establishments are on a scale of almost unrivaled magnificence. The port is separated from the roadstead by moles, which are hollow and bomb-proof, and lined by batteries *à-fleur-d'eau*. There are two ports, the eastern one appropriated to merchant vessels, and called the Port-Marchand, and the Port-Militaire, where are immense magazines, arsenals, ship-building docks, rope- and sail-works, and the convict prison. It is the seat of a maritime prefecture, and possesses a school of hydrography, naval medical school, etc. Pop. 71,000.

Tourniquet. A bandage with a screw attached which, when applied to a wounded limb, stops the flow of blood by external pressure.

Tourville, Aimé-Hilarion de Cotentin, Comte de, an illustrious French seaman, was born at the chateau of Tourville, in Normandy, in 1642, and died in Paris in 1701.

Tourville entered the Order of Malta at 14, and at the age of 18 began to serve in the galleys of the order. Some jealous contemporaries ridiculed him for embracing the profession of arms, and spitefully represented him as an Adonis, more fitted to serve among court ladies than to endure the fatigues of the sea-service. Tourville, however, early made such a reputation in his cruises against the Moors that Louis XIV. sent for him to court, and gave him the grade of *capitaine de vaisseau*.

In 1669 the young captain served, under the Duke de Beaufort, at the relief of Candia, then besieged by the Turks, and further distinguished himself, in 1671–73, in the war with Holland. In 1675 he commanded one of the fleet sent to the relief of Messina, which city had revolted against the Spanish rule.

The following year he was made *chef d'escadron*, and took part in the brilliant expedition of the celebrated Duquesne against the Algerines and Tripolitans, when the corsairs received the most crushing blows which had ever been dealt to them up to that time. He was particularly conspicuous in the bombardment of Algiers.

In 1684 he participated in the bombardment of Genoa, and, four years after, in the expedition against Holland, during which he captured two Dutch men-of-war. Again, in the August of the same year, he nearly ruined the city of Algiers by bombardment.

In 1689 he received the title of Admiral of the Levantine Seas, in which, however, he was destined never to serve, but was immediately put in command of a fleet of 20 vessels, which, in connection with a fleet under D'Estrées, was to support the cause of James II. This combined fleet succeeded, in spite of the exertions of the English, in landing in Ireland a considerable amount of munitions of war and some men.

While in command of the fleet, in July of the year following he encountered an Anglo-Dutch fleet in the Channel, off the Isle of Wight, and in the engagement which ensued he captured 10 vessels and burnt 5, while the French did not lose a single ship. Soon after this success he appeared off Teignmouth, where he destroyed a number of vessels and carried off the valuable cargoes of others.

In May, 1692, Tourville was ordered by Louis XIV., for political reasons not necessary to be detailed here, to sail from Brest to meet the Anglo-Dutch fleet, which consisted of 88 vessels of all rates. Tourville had only about half that number, and remonstrated at being forced to an engagement without reinforcements. He was again ordered to fight the enemy, *fort ou faible*, against any odds. The hostile fleets met just off Cape La Hogue on May 19, 1692, Tourville leading the attack in his flag-ship, the "Soleil Royal," of 106 guns. The engagement was most obstinate; the opposing fleets renewing the fighting for three days. On the 22d Tourville's fleet was completely beaten, but no prizes were made by the allies. The French historians insist that if the minister of marine, Pontchartrain, and his royal master had been willing to wait for the fleet from Toulon, which had been delayed by head-winds, the victory would have been on the side of Tourville.

In 1693 Tourville was made a marshal of France, and the same year fought an action with the Anglo-Dutch fleet off Cape St. Vincent,

in which there were heavy losses and very little decisive gain on either side.

After the peace of Ryswick (1697) Tourville's health failed, and he was obliged to give up active service.

The French navy owed much to Tourville, in morale, organization, and tactics. Saint Simon says he was thoroughly conversant with every duty of the marine service, from that of carpenter to admiral. His justice, coolness, gentleness of manner and politeness to every one; his foresight, prudence, and distinguished courage, led all the young men of the navy to endeavor to serve under him. He was noted for the clearness and decision of his orders, and established an excellent code of naval signals.

The French generally have a man-of-war named after this distinguished sailor.

Tourville had one son, who became a colonel in the army, and was killed at the battle of Denain while still quite a youth.—*E. Shippen.*

Touter (*Eng.*). A slang name for a revenue-cutter. Also applied to an officer of customs.

Tow. To draw a vessel or boat through the water by means of a rope attached to it. An article is *towed overboard* from a vessel by attaching a rope and dragging it through the water. *A tow*, the vessel towed.

TOWAGE. Charges paid for services rendered by a tow-boat.

TOWING-BRIDLE. A heavy chain or hawser to the bight of which a tow-line is attached, when one vessel is being towed by another.

TOWING-HOOK. A large hook sometimes fastened to a towing-bridle, to which the tow-line is attached.

TOWING-PATH, or TOW-PATH. The track on the side of a canal for horses engaged in towing.

TOWING-POST. The timber-head on a tow-boat, to which a hawser is secured in towing.

TOW-LINE. A small hawser used for towing purposes.

Towel. A term in English maritime law, supposed by some to have been derived from the expression "Oster la touaille" in the laws of Oleron.

Malloy writes: "If a mariner shall commit a fault, and the master shall lift up the towel three times before any mariner, and he shall not submit, the master at the next place of land may discharge him."

Toxotes. A genus of acanthopterygious fishes, of which the only species known, *T. jaculator*, is remarkable for its power of spurting water so as to bring down insects from aquatic plants within its reach.

T-plate. A plate of metal cut in the form of the letter T, used for securing different pieces of material together by being bolted or riveted thereto.

Trabaccolo. A coaster of the Adriatic.

Trabaleo. An ancient coasting-vessel.

Trabaria. An ancient name for a small canoe.

Track. The path of a vessel. Also, to tow a boat on a canal by means of men or horses. *Tracks for field-carriage*, wooden tracks placed in a launch or other boat carrying a howitzer, upon which the field-carriage is transported from one end of the boat to the other, as may be required. The *landing-skids* are tracks extending from the bow of the boat to the shore, upon which the howitzer is landed or embarked, when mounted on a field-carriage.

TRACK-BOAT. A boat on a canal moved by towing or tracking.

TRACK-CHART. A chart on a small scale showing the path of a ship during a voyage or cruise.

Trade. The exportation and importation of goods or merchandise. A vessel sailing regularly between the United States and China is said to be employed in the China trade, etc. She may also be said to be in the foreign or the coastwise trade.

TRADER. A vessel which makes regular voyages between certain ports for the purpose of trade or barter.

TRADE-WINDS. The name given to the atmospheric currents of the northern and southern hemispheres, which have a general direction from the northeast in north latitude, and from the southeast in south latitude. They are caused by the combined action of the earth's revolution upon its axis, and the cold air of the polar regions moving toward the equator to take the place of the heated and rarefied air which rises from that portion of the earth's surface.

The direction, force, and regularity of these winds are greatly influenced by the amount of land in the two hemispheres, its character, formation, etc. On account of the excess of land-surface in the northern hemisphere over the southern, the average breadth of the belt of northeast trade-winds is estimated at 9° less than that of the southeast trade-winds. The limits of these winds also vary with the declination of the sun, so that with a high southern declination the northeast trades may extend 1° or 2° south of the equator, while with a high northern declination the southeast trade-winds are found to extend 4° or 5° north of the equator. Between these two winds a region of calms, called doldrums, extends through an average breadth of about 6° of latitude. The proximity of land affects these winds, examples of which are seen on the western coast of Africa, where for nearly 100 miles from the coast the prevailing winds are from the west; and on the western coast of South America, where, on account of the height of the Andes, the trade-winds are not encountered until at a distance of about 400 miles from land.

At the commencement of these winds in both hemispheres, when not under the direct influence of land, their direction is more from the east, and changes toward the north and south as the equator is approached. The average direction of the northeast trade-winds is from E.N.E., while that of the southeast trade-winds is from S.E. by E.

Trail. The *trail* of a field-carriage is that part which projects to the rear of the piece.

TRAIL-BAR. The wooden bar which fits into the socket in the end of the trail of a howitzer-carriage, by which the piece is pointed laterally.

TRAIL-ROPE. A rope attached to the trail of a field-carriage by which it is drawn. Short wooden bars placed through the lay of the rope serve as handles for the howitzer's crew.

Trail-board. A term for the carved work between the cheeks of the cutwater.

Training-level (*Eng.*). A level sometimes used in estimating the elevation or depression of a gun.

Training-pendulum (*Eng.*). An instrument having a pendulum and a level attached, used in pointing guns.

Train-tackle. See TACKLE.

Trajectory. The curve described by a projectile in its flight.

Trammel. A large net.

Tramontana. Literally, from beyond the mountain. The word is applied in Italy to the north wind, blowing from the Alps.

Tran. A Norwegian word for *fish-oil.*

Trankeh. A vessel or large boat of the Persian Gulf.

Transfer. To change officers or men from one vessel to another.

Transire (*Eng.*). A custom-house document issued to a coasting-vessel.

Transit. The passage of a heavenly body across the meridian of the observer. The passage of a heavenly body, or of its shadow, across the disk of a larger body. See ECLIPSE.

TRANSIT INSTRUMENT. A telescope which moves in the plane of the meridian, and therefore adapted for observing the transit of a heavenly body across the meridian.

Transom. One of the horizontal timbers composing the stern-frame. They are secured to the stern-post in the same manner as the floors to the keel; the ends are beveled and trimmed; the fashion pieces are then laid on and bolted to them. The stern-post, transoms, and fashion pieces compose the stern-frame. *Transoms of a gun-carriage*, the parts on the under side of the carriage by which the brackets are connected. They are called the *breast* and *rear* transoms.

TRANSOM-KNEE. A knee bolted to the transom and the frames of the ship, and lying level or in the same direction of the transom. When these knees cross the transom they are called *sleepers.*

Transport. A vessel used for carrying troops or munitions of war. Also, to move or haul a vessel from one part of a harbor to another by the use of hawsers.

TRANSPORTING-BLOCK. A large snatch-block used in transporting a vessel.

TRANSPORTING TRUCKS AND AXLES. Trucks and axles used in moving a gun mounted on a pivot-carriage from one part of the deck to another.

Tranter (*Eng.*). One who sells fish.

Trap-creel (*Eng.*). A basket used in taking lobsters.

Travel. To slip, as a thimble upon a rope. Also, to revolve, as the sheave of a block.

TRAVELER. An iron ring or thimble fitted to slide upon a spar or an iron rod.

TRAVELER-IRON. An iron bar fitted to the deck, upon which the sheet of a fore-and-aft sail travels.

TRAVELING-BACKSTAY. A backstay fitted to a traveler on the topmast, by which the mast is supported at the place to which the topsail-yard is hoisted.

TRAVELING-GUYS. Guys sometimes fitted on small vessels for supporting the jib-boom when the jib is set.

TRAVELING-MARTINGALE. A martingale fitted to the jib-boom of a small vessel, which is in use only when the jib is set. A martingale which was formerly used to support the jib-boom under the jib-tack.

Traverse. The various courses made by a vessel in beating against a head wind, or the irregular track made by a vessel sailing on different courses. A *boat's traverse* is one of the athwart-ship pieces upon which the tracks for a field-carriage are placed. *To traverse a yard*, to place it fore-and-aft.

TRAVERSE-BOARD. A board formerly used in recording the courses made by a ship during a watch. It consisted of a circular piece of board having marked upon it all of the points of the compass, and, upon each point, eight holes bored. The course for each half-hour was noted by placing a peg in one of the holes corresponding to the ship's course.

TRAVERSE-HORSE. See JACKSTAY.

TRAVERSE-QUESTIONS. Cross-examination.

TRAVERSE-SAILING. The case in plane sailing, in which the ship makes several courses in various directions. The solution consists in obtaining an equivalent course and distance from the several courses and distances sailed.

TRAVERSE-TABLE. A table so called from its use in traverse-sailing. It contains the true difference of latitude and departure corresponding to every course (at intervals of a quarter-point and also of degrees) from 0 to a right angle, and every distance up to 300 nautical miles (at intervals of one mile). It is constructed by solving a right-angled triangle, of which one angle represents the course and the hypothenuse the distance; by giving these different and successive values, the corresponding values of the other two sides are found, which sides represent the true difference of latitude and departure.

TRAVERSE-WIND. A wind blowing into a harbor.

Traversier. A small fishing-vessel on the coast of France.

Traversum. The ancient name for a ferry.

Trawl. A line towed by a boat, having at intervals baited hooks attached for catching fish.

TRAWL-BOAT. A boat used in fishing with a trawl.

TRAWL-NET. A small net dragged on the bottom in shoal water for catching fish.

Trayeres. An ancient term for a large boat.

Tread. The whole length of a keel or deck.

Tread Water. To keep the body in a perpendicular position at the surface by treading or walking in the water.

Treble-block. A block containing 3 sheaves.

Trebling. The strengthening planks put on a vessel's bow to withstand the pressure of ice.

Trebuchet. An ancient battering-engine in which stones were used as projectiles.

Treck-schuyt. A Dutch canal-boat.

Treeing. A peculiar appearance of the ice in Arctic regions, caused by refraction, which indicates the proximity of open water.

Treenail. A pin of oak or locust, of a cylindrical form, used as a fastening for plank below the water-line. This kind of fastening is much used in building merchant vessels, but seldom in the naval service.

Trees of a Ship. Chess-trees, cross-trees, and trestle-trees.

Trelawney (*Eng.*). A thin pudding of barley-meal.

Trench the Ballast (*Eng.*). To trim or stow ballast.

Trenchard, Stephen D., Rear-Admiral U.S.N. Born in New York, July 10, 1818. Appointed from New York, October 23, 1834;

receiving-ship, New York, 1835–37; Naval School, Philadelphia, 1839–49.

Promoted to passed midshipman, July 16, 1840; sloop "Preble," West India Squadron, 1841–44; sloop "Fairfield," Home Squadron, 1844–45; coast survey, 1845–49.

Commissioned as lieutenant, February 27, 1847; sloop "Albany," Home Squadron, 1850–52; receiving-ship, Philadelphia, 1853; coast survey, 1854–57; steam-frigate "Powhatan," East India Squadron, 1857–59; commanding steamer "Rhode Island," supply-vessel to Blockading Squadron, 1861–65.

Commissioned as commander, July 16, 1862; two attacks on Fort Fisher, December, 1864, and January, 1865; navy-yard, New York, 1866–69.

Commissioned as captain, July 25, 1866; commanding steam-sloop "Lancaster," flag-ship South Atlantic Squadron, 1869–71.

Commissioned as commodore, May 7, 1871; member Board of Examiners, 1872; light-house inspector, 1873–75.

Commissioned as rear-admiral, August 10, 1875; commanding North Atlantic Station, 1876–78; member of Special Board, 1879–80. Retired July 10, 1880.

Trend. To incline or extend in any direction, as the coast. The *trend* of an anchor is that part of the shank at a distance from the throat equal to the length of one of the arms.

Trennel. See TREENAIL.

Trepang. A name given to the *bêche-de-mer*, used by the Chinese as an article of food.

Trestle-trees. A heavy frame-work of timber placed over the head of a lower-mast and topmast. They rest upon the hounds of the mast, and sustain the weight of the top and cross-trees, and the mast above.

Triangle. A geometrical figure having three sides. Also, small spars lashed together around a mast in the shape of a triangle, used as a stage in painting, scraping, etc.

Triangula. See CONSTELLATION.

Triangulum Australe (*Lat.* "The Southern Triangle"). A constellation half-way between Scorpio and the north pole.

Triatic-stay. A triatic-stay is used in hoisting boats in or out of a vessel. It consists of two large pendants, the upper ends of which are lashed to the foremast and mainmast heads, while to the lower ends, fitted with thimbles, the stay-tackles are hooked. The lower ends of the pendants are held in their proper position by a span.

Tributary. A stream which flows into or supplies another stream.

Trice. To pull up and secure by means of a lashing or *tricing-line*. *Trice up!* the order to raise the heels of the studding-sail-booms before the men lie out on the yards in furling or reefing. A *tricing-line* is any line or rope used to trice up an object with. *In a trice*, in a moment.

Trick. The time which a man remains on duty at the helm.

Trie. An old word, meaning trim.

Triest, the capital of Küstenland and the principal seaport city of Austro-Hungary, is situated on the Gulf of Triest, at the northeast extremity of the Adriatic Sea, in lat. 45° 38′ N., lon. 13° 46′ E. The new part of the town is especially well built. A broad canal, deep enough to float vessels of large burden, runs up from the harbor through this part of the town. Outside of the town is the new lazaretto, one of the best arranged in Europe. The harbor admits vessels of 300 tons to its quays, and vessels of any size anchor safely at a short distance. It is in the form of a crescent, one side of which is formed by the mole, which projects northwest into the sea, and terminates in a broad platform, occupied partly by a fort and partly by an intermittent light 106 feet above the sea. On its north side is a quarantine dock, surrounded with hotels and every other convenience. Close to the harbor are extensive building-docks. Triest is a free port, and possesses a large mercantile navy, and is the headquarters of the Austrian Lloyds, and large numbers of vessels are annually built here. It has an immense import and export trade and extensive manufactories. Population, including suburbs, 110,000.

Trigger. A catch of wood, formerly used in launching, which, upon being struck with a maul, would be displaced and allow the ship to move.

Trigger-finger. The fore-finger of the right hand.

Trig-meat (*Eng.*). Shell-fish.

Trim. To arrange the weights in a vessel in such a manner as to obtain a desired immersion or draft at the bow and stern. Upon this relative draft depends in a great degree the speed of a vessel and the facility with which she can be handled. A vessel is *trimmed by the head* when the draft of water at the bow is greater than at the stern; she is trimmed *by the stern* when the draft at the stern is greatest. Each vessel has a certain trim most favorable to her sea-going qualities.

Ballast and cargo stowed in bulk requires to be *trimmed* or spread from under the hatches into the more inaccessible parts of the hold.

Sails are *trimmed* by changing the position of the yards, in order that the wind may act upon them at the proper angle; also, by hauling the sheets home and hoisting the yards to their proper places, in order that the sails may receive the full force of the wind. A boat is *trimmed* by keeping it in an upright position by means of the crew or cargo. A jacket is said to be *trimmed* when the wearer of it is flogged with a rope's end.

Trink. An old apparatus for catching fish.

Trip. A passage made by a vessel from one port to another. *A round trip* is the whole voyage. An anchor is *a-trip* when it is raised clear of the bottom. *To trip a light yard* is to pull it into a perpendicular by means of the tripping-line, preparatory to lowering it to the deck.

TRIPPING-LINE. A small line attached to the snorter of a topgallant- or royal-yard, reaching to the deck, by which the yard is tripped, the lower lift and brace cleared of the yard-arm, and the yard guided to the deck.

Triple-star. Three stars in such apparent proximity as to resemble a single star.

Tripoli. The capital of the state of Tripoli, on the north coast of Africa. Lat. 32° 53′ 54″ N.; lon. 13° 11′ E. It stands on a rocky promontory washed by the sea on the north and east, and connected with the mainland on the south and west by a sandy plain. It is defended on the land side by a lofty wall flanked with bastions, and on the sea-front by a formidable line of batteries. The trade has the advantage of the only

good harbor for several hundred miles on the coast. It is not over 6 fathoms deep, but has capacity to admit whole fleets of merchant vessels in the outer roads, where there is good anchorage in from 16 to 18 fathoms. About 1000 vessels clear this port annually. Pop. 20,000.

Tripping-valve. A valve for releasing the fluid and relieving the pressure in a hydraulic press or jack.

Trip-shaft. In the steam-engine, a shaft carrying devices for *tripping* or detaching cut-off valves from the main valve-gear in cases where they are actuated, in part, thereby.

Troacher (*Eng.*). One who receives and deals in smuggled goods.

Troite. An obsolete term for the cuttle-fish.

Troll. To fish by drawing the hooks through the water.

Trombone. A name formerly applied to the blunderbuss, from the shape of its muzzle.

Tromp, Martin Van, the celebrated Dutch admiral, was born at Briel in 1597, and died in 1653. When only 11 years old he served on board of a frigate commanded by his father. The latter was killed in an engagement with the French, who took the vessel, and detained the boy on board ship as a *mousse* for three years. When he obtained his liberty he rose rapidly in the Dutch navy, being lieutenant of a line-of-battle ship at 25, and two years later captain of a frigate. A vice-admiral at 40, he commanded a Dutch fleet which, in 1639, totally defeated a Spanish fleet of superior numbers and weight of metal. This success made him very popular at home, and he was also created a noble of France from the date of his victory. In 1652, war breaking out between Holland and England, Van Tromp, in command of the fleet, met Admiral Blake, and in an engagement with him lost 2 line-of-battle ships. Dissatisfied with this result, the States-General caused Van Tromp to be relieved in his command by Van Ruyter. The former was, however, restored to command in a few months; and, on December 10, 1652, defeated the English admiral, driving him into the Thames, and causing great alarm in London. It was then that Van Tromp swept down the Channel with a broom at his mast-head. After this he had many encounters with the English, with varying fortunes, fighting some gallant actions.

At last he was intercepted by Blake near Portland Bill, and badly defeated. In command of a refitted fleet he again had an encounter with the English fleet, under Monk, upon the Dutch coast. In this action he was mortally wounded, but cried out to his crew, "Bear up, my boys. Conduct yourselves so that my death may be as glorious as my life has been!"

The States-General ordered a medal struck in commemoration of Van Tromp, and erected a splendid monument to him at Delft, where he was buried.

Tromp's son, Cornelius, who died in 1691, rose high in the Dutch navy, having attained the rank of vice-admiral. He served principally against the Moorish pirates, and the English and Swedes.

In consequence of a supposed dereliction in duty during the action in the Downs with the English, in July, 1666, Ruyter, under whom he was serving, demanded his dismissal, which was granted; but after two years he was reinstated, and on Ruyter's death succeeded to the command of the Dutch navy. Upon the peace with England, in 1675, he visited that country, and was received most courteously, Charles II. making him a baronet.—*E. Shippen.*

Troop-boat. A boat of great capacity used in the transportation of troops.

Troop-ship. A large ship, either built for the purpose or converted from a frigate or line-of-battle ship, used in carrying troops.

Tropic-bird. The *Phaeton æthereus.* Also called the *boatswain*, on account of the resemblance of its tail to a marling-spike.

Trough of the Sea. The depression of the water between two waves.

Trounce. An obsolete word, meaning to punish.

Trouncer (*Eng.*). An old term for a waister.

Trout. A fresh-water fish of the genus *Salmo*, variegated with spots, and esteemed most delicate food. The brook-trout of America is *Salmo fontinalis*, the lake-trout, *S. confinis.* The *Salmo trutta*, sea-trout, is similar to the salmon in its habits.

Trow (*Eng.*). A boat used on the river Tyne for catching salmon.

Truce. A temporary suspension of hostilities between opposing forces, agreed upon by the commanders for the purpose of negotiation, etc. The desire for such suspension is indicated by showing a white flag, or a *flag of truce*, and the approach of persons under such a flag toward the enemy's lines, or of a vessel to a hostile coast, insures safe conduct among all civilized nations. See FLAG.

Truchman. See TRUGMAN.

Truck. Small articles used in barter. A wheel of a gun-carriage. A circular piece of wood placed on the head of a mast or flag-staff, in which the sheave for the signal-halliards is placed. A fair-leader is called a *leading truck.*

Truckle. The name given on the Welsh coast to the coracle, a kind of boat consisting of a light frame-work covered with leather or oil-cloth.

True-blue. An expression denoting loyalty and sincerity.

True-tide (*Eng.*). A tide which sets in a regular direction.

True Water (*Eng.*). The exact depth of water.

Truff (*Eng.*). A trout.

Trugman. An old term for an interpreter.

Trumpet-fish. A sea-fish; the *Centriscus scolopax;* so called from its tubular muzzle; bellows-fish; snipe-fish.

Trundle-head. The lower drum-head of a double capstan.

Trundle-shot. A projectile formerly used, about a foot and a half in length, pointed at both ends.

Trunk. A small net used in catching lobsters and crabs. Also, a species of turtle.

Trunk-cabin. A cabin half below and half above the level of the spar-deck.

Trunk-engine. A very compact form of steam-engine, in which the connecting-rod is jointed directly to the piston, without the intervention of a piston-rod or cross-head. The rod works within a hollow cylindrical piece, or *trunk*, of sufficient diameter to permit its free oscilla-

tion, which is attached to the piston, and passes from the cylinder through a stuffing-box, acting, also, as a guide. See MARINE STEAM-ENGINE.

Trunk-fish. The *Ostracion*, a fish having a covering of solid bony plates.

Trunnion. One of a pair of cylindrical projections attached to or formed upon the opposite sides of a gun, oscillating steam-engine cylinder, etc., at right angles to its axis, so that the body, when supported thereby in suitable bearings, is free to oscillate about the trunnion axis.

TRUNNION-GAUGE. An instrument used to measure the diameter of the trunnion of a gun.

TRUNNION-LEDGE AND LEVEL. A small shelf attached to the trunnion of a heavy gun, which being placed in a horizontal position by means of a spirit-level, indicates the degrees of elevation or depression.

TRUNNION-RING. A ring formerly placed upon a gun a little forward of the trunnions.

TRUNNION-RULE. A rule used in the inspection of guns for measuring the distance from the trunnions to the base-ring.

TRUNNION-SQUARE. An instrument used in inspecting guns for ascertaining if the axis of the trunnions is perpendicular to the axis of the bore.

Truss. A heavy iron fixture by which the centre of a lower-yard is held in position at the mast, and which forms the centre of motion of the yard. Before the invention of the iron truss, rope trusses were used, with which the yard was kept in the required position by means of tackles fitted to the lower ends of the truss-pendants. *Truss up*, to brail up a sail.

TRUSS-HOOP. A heavy iron band used in mast-making.

TRUSS-PARREL. That part of a rope truss which passes around the yard.

TRUSS-PENDANT. That part of a rope truss which is passed around the mast and to which the truss-tackles are fitted.

TRUSS-TACKLE. One of the tackles by which the pendants of a rope truss are hauled taut.

Truxtun, Thomas, Commodore U.S.N. Born in Jamaica, L. I., February 17, 1755. He went to sea early in life, and during the war of the Revolution established a high character for courage and nautical skill in command of the private armed vessels "St. James," "Mars," and "Independence." He was among the first to discuss and point out the value of the Gulf Stream to navigation. He was a fine navigator and prime seaman. In 1794 he published from "the Stone House, South Second Street, Philadelphia," "A Treatise on Latitude and Longitude," with an appendix on the formation of our (then) infant navy, and a plate showing "Truxtun's System of Masting a 44-Gun Frigate." He was commissioned a captain in the U. S. navy in 1794. February 9, 1799, while in command of the frigate "Constellation," he captured the French frigate "L'Insurgente." February 1, 1880, still in the "Constellation," he fought and drove into Curaçoa, in a sinking condition, the French frigate "La Vengeance," being prevented, by the loss of the "Constellation's" mainmast, from taking possession of his prize. For this action Congress awarded him a gold medal. He fought the first battle under the present naval organization, which he was largely instrumental in establishing. After the quasi-French war he commanded the West India Station, and finally was ordered to hoist his flag on the "President," 44, and assume command of the Mediterranean Squadron, when, some question arising as to his being allowed a captain to command the flag-ship, he resigned his commission, in 1802, and took up his residence in Philadelphia, of which city he was subsequently elected sheriff. He died May, 1823. His remains lie in Christ Church burying-ground, Fifth and Arch Streets, Philadelphia.

Try. A word meaning to *lie to*, but now seldom used. From this the *trysails* received their name. *To try back for a bend*, to pay back enough of a hawser to make a bend. *To try down*, to separate oil from blubber by melting. *To try the range*, to ascertain the distance of an object by firing at it.

TRYSAIL. A fore-and-aft-sail set on the fore and main lower-masts of a ship. It is bent to a gaff, and is considered a storm-sail, or one under which a vessel can lie-to easily during a gale. See TRY.

TRYSAIL-BRAILS. Ropes used in taking in a trysail.

TRYSAIL-GAFF. The gaff to which a trysail is bent.

TRYSAIL-MAST. A small mast placed abaft a lower mast, to which a trysail is bent by means of hoops.

TRYSAIL-OUTHAUL. A rope by which the head of a trysail is hauled out on the gaff.

TRY-WORKS. The boilers and furnaces used on whale-ships for trying down blubber.

T-square. A rule having a cross-piece at one end placed at right angles; used in draughting for making parallel lines.

Tub. A *division-tub* is furnished to each division of a ship-of-war, in which fresh water is placed during action. A *fire-tub* is placed on the berth-deck during action at the place where the empty passing boxes are received from the deck above. It is partially filled with water, and is fitted with a grating near the top. As a precaution against explosion from any fire that may be in the box, each one is inverted and struck over the tub before being refilled. *Grog-tub*, the tub in which the daily allowance of grog was formerly mixed, and from which it was served to the crew. *Match-tub*, a small tub having holes bored in its upper head, in which slow-matches were formerly placed during action.

Tube. A hollow cylinder of any material, the length of which considerably exceeds its diameter. A pipe. *Quill-tubes*, quill-primers. See PRIMER.

TUBE-EXPANDER. A tool for stretching or expanding the end of a tube in direction of its diameter, so as to cause it to fit snugly, and confine it, air-tight, to a *tube-sheet* or *-plate* by forming a *bead* on either side thereof.

TUBE-SHEET, or TUBE-PLATE. One of a pair of sheets of metal containing accurately-bored holes, to which the ends of the tubes of a steam-boiler, condenser, or other fluid-tight apparatus are secured, either by expanding or packing their ends. These sheets are firmly built in, and form part of the structure.

TUBULAR BOILER. A boiler in which a great portion of the *heating surface*, or the surface exposed to fire, is composed of tubes through or around which the heated gases of combustion circulate.

Tub-fish. A fish of the genus *Trigla* (*T. hirundo*); sapphirine gurnard.

Tuck. That part of a vessel in which the after extremities of the outside planking end, either on the wing-transom or against the tuck-timber.

TUCK-RAIL. A rail placed at the upper part of the wing-transom, forming an abutment and finish to the ends of the plank in square-sterned vessels.

Tucker, Samuel, a brave, able, and successful naval officer of the Revolution. Born in Marblehead, Mass., November 1, 1747; died at Bremen, Me., March 10, 1833. Son of a ship-master. He was apprenticed at 11 on board the "Royal George," and before the Revolution was a captain, sailing from Boston to London. Commissioned a captain in the Revolutionary navy, March 15, 1777, he took command, in November, of the frigate "Boston," in which, in February, 1778, he took out John Adams, minister to France. He took many prizes in 1779; aided in the defense of Charleston, S. C., and was a prisoner from its capture, in May, 1780, till June, 1781, when he took command of the "Thorn," and made many prizes. At the close of the war he received the thanks of Congress for his services. In 1792 he settled in Bristol, Me. In the war of 1812 he captured, by a ruse, a British vessel which had greatly annoyed the shipping of Bristol and vicinity. He was several times a member of the Legislatures of Massachusetts and of Maine.

Tug. A small steamer used for towing. Also, to row with great exertion and make but little progress.

Tugg (*Eng.*). A heavy cart for hauling ship-timber.

Tumble Home. To narrow in. Said of the sides of a vessel when they incline inboard after reaching a certain height.

Tumbler. An attachment to the jaws of a gaff to prevent chafe upon the mast. Also, a name sometimes given to the porpoise.

Tumble Up. To hurry on deck from below.

Tumbling Sea. A rough, irregular sea.

Tum-tum. A dish made in the West Indies from boiled plantain.

Tungula. The name of a small boat in the vicinity of Borneo.

Tunis. The kingdom and city of Tunis possesses, as its navy, 2 small armed steamers, an aviso of 500 tons, with 8 guns and engines of 160 horse-power, and a transport of 400 tons, with 2 guns and 140 horse-power. This small force is soon to receive an accession of 2 ironclad monitors, now being built in France.

Tunis, the capital of the state of the same name, is situated at the mouth of the Mejerda, on the west side of an oval lagoon connected by a narrow strait with a bay of the same name. It is surrounded by walls and defended by a strong castle, which completely commands the Goletta, or narrow strait already mentioned. The principal exports are oil, soap, wool, hides, cattle, sponges, senna, wax, gold-dust, etc. The manufactures are linen and woolen cloths, red woolen caps, pottery, and various essences. Lat. 36° 48′ N.; lon. 10° 24′ E. Pop. 125,000.

Tunny. A fish of the genus *Thynnus*, of the mackerel family, similar, in form, to the mackerel, but much larger, rounder, and with a shorter snout. It is one of the largest of fishes, tunnies weighing 1000 pounds not being rare in the Mediterranean. The tunny is considered excellent food.

Turbot. A flat-fish of the genus *Rhombus* (*R. maximus*), with a body nearly circular. It grows to the weight of 20 or 30 pounds, and is much esteemed by epicures. The name is applied in Scotland to the halibut.

Turkey, Navy of. The present effective armored fleet of this nation comprises 15 large ships of various types, and a small fleet of gunboats and river monitors. The ships are for the greater part of English and French build, several being of modern type, furnished with Armstrong guns, and engineered by Englishmen. Their principal officer, Hobart Pasha, was formerly an English naval officer. The Turkish navy also possesses 3 old wooden ships of the line, mounting an aggregate of 254 old smooth-bore guns; 5 wooden frigates, and 7 corvettes, mounting about 300 guns; also 21 smaller craft carrying about 80 guns. There are also 4 paddle-wheel vessels, mounting 4 guns each; 3 sailing-cruisers with an aggregate of 8 guns; and 22 dispatch-boats, mounting 64 guns in all. The most powerful ship is the "Mesoodiyeh," built by the Thames Ship-building Company, with machinery constructed by Messrs. Maudslay, Sons & Field. The length between perpendiculars is 332 feet; extreme breadth, 59 feet; depth of hold, 36 feet; mean draft, 25 feet; displacement, 8994 tons. The armor-plating on the sides is 12 inches thick, backed by the same thickness of East India teak. The armament consists of twelve 18-ton guns on the gun-deck, two 6½-ton guns on the forecastle and one of the same weight aft on the poop. The navy is represented in the cabinet by a minister of marine, and in the divan or chancellery by an assistant secretary. The service is divided into four sections,—personnel, matériel, naval constructions, and health. The *personnel* is constituted as follows:

Executive officers: vice-admirals, 6; rear-admirals, 11; captains of ships, 131; captains of frigates, 23; captains of corvettes, 54; lieutenant-captains of corvettes, 289; lieutenants of ships, 228; ensigns, 187. Total executive officers, 929. Mechanicians, 480; pay-officers, 33; medical officers, 47; staff-officers, 20. Marine officers: colonels, 2; lieutenant-colonels, 7; other officers, 82; total, 91. Total officers, 1600. Seamen, active, 6000; marines, 4500. Total officers and men, 12,100. The navy is recruited partly by voluntary enlistments and partly by conscription.

Turk's-head. An ornamental knot made in the upper end of a man-rope. See KNOT.

Turn. *To take or catch a turn*, to pass the bight of a rope over a pin or cleat in order to secure it. *Turn ahead*, to go ahead slowly, referring to the engine of a steamer. *To turn turtle*, to capsize. *To turn in*, to go to bed. *To turn in a dead-eye* is to fasten a shroud around it. *Turning-room*, sufficient room for a vessel to turn. *Turn in the hawse*; see HAWSE. *Turn of the tide*, the change from flood to ebb, and *vice versa*. *To turn out*, to get up. *Turn out the guard!* the order for the marines to form in line on the quarter-deck. *To turn over men, stores*, etc., to place them under the charge of another officer. *Turn the glass!* or *Turn!* the order to turn the time-

glass, in heaving the log, when all of the stray-line has run out. *To turn to windward*, to work to windward. *Turn up the hands!* an order for all hands to come on deck.

Turnbuckle. A link for connecting two parts of a bar or rod together, and adjusting the whole to proper length or tension. Both ends of the link may be fitted to screw-threads, one right-handed and the other left-handed, or one end may be provided with a screw-thread and the other with a swivel. The link is turned by means of a bar or a wrench.

Turner, Thomas, Rear-Admiral U.S.N., is a native of Virginia. Appointed midshipman from Virginia, April 21, 1825; attached to frigate "Constellation," Mediterranean Squadron, 1827; sloop-of-war "Warren," Mediterranean Squadron, 1830.

Promoted to passed midshipman, June 4, 1831; frigate "Constellation," Mediterranean Squadron, 1834, and frigate "Delaware," same squadron, 1835.

Commissioned as lieutenant, December 22, 1835; frigate "Columbus," East India Squadron, 1840; receiving-ship at Philadelphia, 1843; sloop "Albany," Home Squadron, 1847. Lieut. Turner was actively engaged in the war with Mexico, and was present at Tuspan, April 7, 1847; receiving-ship at Philadelphia, 1850; frigate "Congress," Brazil Squadron, 1851–53; on ordnance duty, 1854–57.

Commissioned as commander, September 14, 1855; commanding sloop-of-war "Saratoga," Home Squadron, 1859–60. Commander Turner was in command of "Saratoga" in the engagement between that vessel and two Spanish steamers, the "Marquis of Havannah" and "General Miramon," in the harbor of Anton Leyardo, Mexico, when they were captured, March 6, 1860, at midnight.

Commissioned as captain, July 16, 1862.

Commissioned as commodore, December 13, 1863; commanded frigate "New Ironsides," special service, 1863; commanded frigate "New Ironsides" in the attack upon Forts Sumter, Moultrie, and Beauregard, in Charleston harbor, April 7, 1863. Admiral Dupont was on board the "New Ironsides," and commended Commodore Turner for the judgment and ability with which he handled his vessel. Special duty, New York, 1864–65; special duty, Philadelphia, 1866–67; on ordnance duty, Philadelphia, 1868.

Commissioned as rear-admiral, May 27, 1868; commanding Pacific Fleet, 1869–70. Retired April 21, 1870.

Turnpike-sailor (*Eng.*). An impostor, dressed as a sailor and asking charity.

Turret. See IRONCLADS.

Turtle. The popular name of a marine reptile having fin-like paddles instead of legs, suited for swimming and not for walking. They deposit their eggs in the sand on the beach, two hundred being sometimes found in a single nest. Some of the species feed on aquatic plants, others on crustaceans, mollusks, and fishes. The flesh of those who feed on vegetable matter is much esteemed for food.

The *green turtle* (*Chelonia mydas*) attains a weight of 700 to 800 pounds: the name is derived from the color of its fat. The *hawkbill turtle* is valuable as yielding the best tortoise-shell. *To turn turtle*, to capsize.

TURTLE-CRAWL. A shallow pond where turtles are kept.

TURTLE-PEG. A kind of spear for taking turtle.

Tusk (*Eng.*). A fish,—the *Brosmus vulgaris.*

'Tween-decks. A contraction of *between-decks.* The lower deck of a merchant vessel. The space between two decks.

Twice-laid Rope. Rope made from second-hand yarns.

Twiddling-line. A former name for a line used to steady the wheel when not in use.

Twig. A slang term, meaning to know or observe.

Twig-ait (*Eng.*). A place where osiers grow.

Twilight (Sax. *tweon-leoht*, doubtful light). Twilight begins and ends when the sun is about 18° below the horizon; and its duration, therefore, varies with the latitude, for the time which is required for the sun to rise through 18° vertically depends upon the inclination of its diurnal path to the horizon of the place, and is greater as this inclination is less,—*i.e.*, the higher the latitude. The twilight is the best time for observing the altitudes of the stars at sea, for then the horizon is in general clearly visible and distinctly marked.

Twine. Small cord.

Twin-screws. A pair of screw-propellers arranged with one under each quarter of a vessel, and driven by separate engines, so that one may back while the other is going ahead, or that both may act together in either direction. This arrangement gives great handiness to the ship, and for light-draft vessels two screws are more efficient in a seaway than a single one.

Two-blocks. The condition of a tackle when both blocks have been drawn together.

Two-handed Fellow. A name applied to a man who has served both as a sailor and a marine.

Twy. The name given to a sudden squall on some parts of the English coast.

Tye. That part of the purchase for hoisting a topsail-yard which is attached to the yard, and passes through the sheave-hole in the mast or the tye-block at the mast-head.

TYE-BLOCK. A block sometimes used at the head of a topmast in place of a sheave in the mast, through which the topsail-tye is rove. A tye-block is sometimes used on the topsail-yard in order to increase the purchase, the standing-part of the tye being fastened to the mast-head.

Tymoom. A boat used on Chinese rivers.

Tyndarides. The ancient name for the luminous appearance now called *corposants.*

Typhoon (Gr. *tuphōs*, a violent wind which whirls up clouds of dust or mist). The name given to the hurricanes or revolving storms which occur in the China Sea and Indian Ocean at the seasons of the change of the monsoons. See STORM, REVOLVING.

U.

U. Abbreviation for *you* in the U. S. General Service Signal Code. In the log-book, *u* denotes *ugly threatening weather.*

Udometer. A rain-gauge.

Ugly. Disagreeable; dangerous; threatening,—applied to the weather or sea.

Ulcus. An old term for the hulk of a ship.

Uliginous. Muddy; slimy.

Ultra Mare. Beyond the sea.

Ultra-zodiacal. Beyond the limits of the zodiac.

Umber. An African bird of the family *Ardeidæ*, allied to the storks, but having a compressed bill with a sharp ridge.

Umbrina. A genus of acanthopterygious fishes, common in the Mediterranean, and found also upon the shores of England. The flesh is white and of good flavor, and some of the species are remarkable for their beauty.

Under. *Under canvas*, under sail. *Under foot*, under the bows,—said of the anchor when the chain is nearly perpendicular. *Under manned*, short-handed; having an insufficient number of men. *Under masted*, having masts too short or too slender to allow of sufficient sail being carried. *Under sail*, propelled by the action of the wind on the sails. *Under steam*, propelled by steam-power. *Under the lee*, sheltered from the wind by some intervening object. *Under the sea*, lying-to in a gale, and making bad weather of it. *Under way*, see WAY. *To under-run a hawser*, to haul a boat along under a hawser, lifting it out of the water.

Under-beveling. See BEVEL.

Under-bright. The bright streak which often appears under clouds near the horizon.

Under-current. A stream which sets beneath the surface-water of the sea whilst that is either in a quiescent state or moving in a contrary direction. Swift rivers may run out at the surface whilst the flood-tide runs in below.

Under-tow. An under-current found at the mouths of rivers and in tide-waters.

Underwriter. An insurer; so called from his underwriting or subscribing the policy of insurance. See MARINE INSURANCE.

Undines (Lat. *unda*, a wave). A name given in the fanciful system of the Paracelsists to the elementary spirits of the water. They are of the female sex, and intermarry with human beings.

Undress-uniform. See UNIFORM.

Unicorn. An old name for a howitzer.

Unicorn-fish. The sea-unicorn, or narwhal.

Uniform for the U. S. Navy. *Full-dress uniform, to be worn on occasions of special ceremony.*—Body-coat, epaulets, cocked hat, sword with sword-knot, and blue cloth pantaloons.

Undress-uniform for official visits.—Frock-coat, epaulets, cocked hat, sword with knot, and blue cloth or white drilling pantaloons to suit the season, weather, or climate.

Service-dress uniform.—Frock-coat with shoulder-straps, cap, pantaloons, blue or white, to suit the seasons of the year, weather, or climate.

Officers making special official visits of ceremony to the President of the United States, the Secretary of the Navy, or to foreign authorities and vessels of war, wear the full-dress uniform.

When making an official visit to the President of the United States, the Secretary of the Navy, or to the heads of other Departments of the government, and to foreign authorities and vessels of war, officers wear the undress-uniform or the service-dress, as occasion may require.

Officers serving on courts-martial, courts of inquiry, boards of examination or special boards, or when attending as witnesses before courts-martial or courts of inquiry, or in any other capacity, wear the service-dress uniform, without swords, unless otherwise specially directed by competent authority.

Officers, in their social intercourse, when it is requisite for them to appear in evening-dress, may wear a body-coat of blue cloth, after the prevailing style of a civilian's dress-coat, with rolling collar, five navy buttons on each side, two at the waist behind, and two at the bottom of the skirt. The lace and corps distinctions on the cuff, same as on full-dress coats. This coat may be worn with or without epaulets, but not with shoulder-straps or sword.

It is optional with officers to wear their uniform while on duty in the Navy Department, at the Observatory, Hydrographic Office, or on light-house duty ashore.

Service-dress uniform is worn by all officers when attached to any vessel of the navy or coast survey, to any navy-yard or station, or to any hospital or other naval establishment, for duty, unless when absent on leave.

Chaplains, when performing divine service, may wear either the vestments of the church to which they belong, or the uniform prescribed in the regulations.

Gloves worn with uniform are always to be white.

Officers on furlough will not wear their uniform, and officers are strictly prohibited from wearing any part of it while suspended from duty by sentence of a court-martial.

Officers are forbidden to wear any part of their uniform with citizen's dress. They must wear the whole of their uniform or none.

Full dress.—The full-dress body-coat for all commissioned officers is of navy-blue cloth, swallow-tailed, double-breasted, and lined with white silk serge; two rows of large navy buttons on the

breast, nine in each row ; standing collar, to have one strip of gold-embroidered white-oak leaves for admiral and vice-admiral; to have a strip of navy gold lace one inch wide around the top and down the front for rear-admirals, commodores, captains, and commanders, and one-half inch wide for lieutenant-commanders, lieutenants, masters, and ensigns.

All staff-officers wear the same widths of gold lace around the top and down the front of the collars of their full-dress body-coats as prescribed for line-officers with whom they have relative rank, respectively.

Midshipmen, after graduation, are allowed a full-dress double-breasted coat, nine buttons in each row, with a gold cord around the sleeve, and an anchor in gold embroidery on each side of the collar.

The full-dress coat is worn only with epaulets, cocked hat, sword and sword-knot.

Midshipmen at the Naval Academy wear a strip of lace one-eighth of an inch wide around the outer edge of the collar of their parade-jackets.

The undress and service frock-coat.—The undress and service frock-coat for all commissioned officers is of navy-blue cloth, faced with the same, and lined with black silk serge; rolling collar; double-breasted, with two rows of large navy buttons on the breast, nine in each row.

Frock-coats for midshipmen are the same as for commissioned officers, except that the buttons will be of medium size only.

The uniform coat for boatswains, gunners, carpenters, and sail-makers is a frock-coat similar in every respect to the frock-coat of the line and staff commissioned officers.

Clerks and mates wear a double-breasted frock-coat, with nine navy buttons of medium size on each side.

Sleeve ornaments.—An admiral has three, a vice-admiral two, and a rear-admiral one, strips of gold embroidered white-oak leaves on the cuff of the full-dress coat. The undress-coat of an admiral has one two-inch, and three half-inch strips of gold lace on the cuffs. A vice-admiral has but two strips of half-inch lace above the two-inch strip. A rear-admiral has only one strip.

Commodores wear one strip of two-inch gold lace on the cuffs of both full-dress and undress-coats; captains, four strips of half-inch lace; commanders, three; lieutenant-commanders, two, with a strip of quarter-inch lace between; lieutenants, two; masters, one; ensigns, one quarter-inch strip; and midshipmen a gold cord.

Staff-officers wear the same as line-officers with whom they rank, the corps being distinguished by differently-colored cloth between the strips of gold lace. Medical officers wear cobalt-blue; paymasters, white; engineers, red; naval constructors, dark violet; professors of mathematics, olive-green.

All line-officers wear a five-rayed star above the gold lace on the cuffs, the star for an admiral having a steam-frigate raised in the centre.

Epaulets, shoulder-straps, etc.—All commissioned officers above the rank of ensign wear two gold-bullion epaulets, with their respective strap ornaments on the frogs.

All shoulder-straps are of navy-blue cloth with a border embroidered in gold. The centre and end ornaments, corps distinctions, and indications of rank are as follows:

Admiral, four silver stars, with a gold foul-anchor under each of the outer stars.

Vice-admiral, three stars, with an anchor under the centre star.

Rear-admiral, two stars, with a silver foul-anchor in the centre.

Commodore, one star, with a foul-anchor at each end of the strap.

Captain, a silver spread-eagle, with a foul-anchor at each end of the strap.

Commander, two silver oak-leaves, with a foul-anchor in the centre.

Lieutenant-commander, two gold oak-leaves, with a foul-anchor at each end.

Lieutenant, two gold bars at each end, a foul-anchor in the centre.

Master, one gold bar at each end, a foul-anchor in the centre.

Ensigns and midshipmen wear shoulder-knots in lieu of straps or epaulets.

Staff-officers wear the same strap as the line-officers with whom they hold relative rank, with the following exceptions: medical officers omit the anchor; paymasters substitute an oak-sprig for the anchor; engineers, a device formed of four oak-leaves in the form of a cross; naval constructors, two oak-leaves and an acorn; chaplains, a silver cross; professors of mathematics, one oak-leaf and an acorn; secretaries, the letter S in silver.

In lieu of shoulder-straps, boatswains and gunners wear on each side of the collar a gold star; carpenters and sail-makers, a gold diamond.

Cocked hat, cap, etc.—All commissioned officers above the grade of ensign wear a black cocked hat bound with black silk lace, and ornamented with a gold loop and a black cockade. Cocked hats are always worn with epaulets.

The cap is of dark-blue cloth, with a plain black silk band, and may be worn with a black glazed, or a white linen cover, as circumstances demand. The cap ornament for all commissioned officers and midshipmen is a silver shield, with a silver eagle and two crossed anchors in gold. A double-looped gold cord is also worn. Warrant-officers wear two gold anchors crossed. Mates wear a plain, vertical, gold anchor.

Pantaloons.—For full-dress the pantaloons of all commissioned officers is of blue cloth, with a heavy strip of gold lace down the outer seams. For undress and service-dress, pantaloons are of blue cloth or white duck.

Vests.—Single-breasted, standing collar, nine small buttons, and made of navy-blue cloth or white duck.

Jackets.—Jackets may be worn as service-dress, except at general muster, or on occasions of special ceremony. They are of navy-blue cloth, with a rolling collar, and trimmed in the same manner as the service-coat. White linen jackets without straps and sleeve ornaments may be worn in warm weather.

Sack-coats.—Single-breasted sack-coats with standing collar, cuffs trimmed with black lace in lieu of gold, with the shoulder-strap device (omitting the duplicate end device) on the collar, may be worn under certain circumstances.

Overcoats.—Overcoats are of heavy navy-blue beaver or pilot cloth, with or without a cape; double-breasted, five buttons on each breast.

On the collar are worn the devices authorized for sack-coats. Mates, clerks, and warrant-officers wear no device on their overcoats.

Swords, sword-belts, etc.—The sword has a cut-and-thrust blade, half-basket hilt, white grip, and a black leather scabbard, with mountings of yellow gilt. Midshipmen may wear a dirk.

The full-dress sword-belt of admiral and vice-admiral is of navy-blue cloth with a gold cord around the edge, and a strip of gold-embroidered white-oak leaves running through the centre. The full-dress sword-belt of all other commissioned officers is of blue webbing with gold cord woven in, the arrangement of the gold cord indicating the rank of the wearer. The service-dress sword-belt for all officers is of plain black glazed leather.

The sword-knot for all commissioned officers is a gold strap 24 inches long, including the tassel, gold slide, tassel of twelve gold bullions and basket-worked head.

Union. The upper inner corner of a flag, which generally contains objects emblematical of the country represented by the flag. Thus, the union of the flag of the United States is a blue field containing a white star for every State. In small flags there are ordinarily but thirteen stars,—one for each of the original States. When a ship hoists her flag *union down* it is a signal of distress.

Union Coupling. A contrivance for joining two sections of small pipe, so that they may be readily connected or disconnected without disturbing other joints. It consists mainly of a pair of cylindrical shells, screwed or otherwise secured to the ends of the pipes, one of which, the *male part*, has a screw-thread cut upon its outer surface, and the other a flange which retains a flanged ring, free to turn and provided with suitable projections (usually forming a hexagon) to receive a wrench, and on the interior surface of which is cut a *female screw-thread* matching the thread of the male part. The joint between the two parts is made fluid-tight by washers or packing of leather, gum, cotton-wicking, etc. See HOSE-COUPLING.

Union Jack. A small flag corresponding in appearance to the union of the national flag. See JACK.

Universal Coupling. A coupling which permits the parts united to assume various angular relations to each other.

Universal Joint. A contrivance for coupling rotating shafts whose axes intersect each other in a point. A joint, or system of joints, so arranged between two pipes or sections of pipe that their axes may be turned in any direction relatively one to the other.

Unrig. To strip of rigging.

Unukalhai. The star *α Serpentis.*

Up. The helm is *up* when the tiller is borne over to windward. *Up anchor!* the boatswain's cry to the men to take their stations for weighing anchor. *Up-and-down*, perpendicular; vertical. *Up boats!* the order to the men to take their stations for running the boats up to the davits. *Up courses!* the order to haul up the courses.

Uphroe. A wooden slat with a range of holes through which the small lines of a crow-foot are rove.

Upper Deck. The spar-deck.

Upper-works. The ship's frame above the water-line.

Upshur, John H., Commodore U.S.N. Born in Virginia, December 5, 1823. Appointed from Virginia, November 4, 1841; attached to frigate "Congress," Mediterranean Squadron, 1841–43; sloop "St. Mary's," Mediterranean Squadron, 1843–46; Home Squadron, during Mexican war; in the Naval Battery, during the bombardment of Vera Cruz; Naval School, 1847.

Promoted to passed midshipman, August 10, 1847; frigate "Cumberland," Mediterranean Squadron, 1849–50; ordnance duty, 1852; store-ship "Supply," East India Squadron, 1853–56.

Promoted to master, 1855.

Commissioned as lieutenant, September 14, 1855; ordnance duty, Washington Navy-Yard, 1856–57; sloop "Cumberland," coast of Africa, 1858–59; instructor at Naval Academy, 1859–60; North Atlantic Blockading Squadron, 1861; at capture of forts at Hatteras, N. C.; steam-frigate "Wabash," South Atlantic Blockading Squadron, 1861; present at battle of Port Royal; commanding steamer "Flambeau," South Atlantic Blockading Squadron, 1862–63; several expeditions up the rivers of South Carolina.

Commissioned as lieutenant-commander, July 16, 1862; commanding steam-frigate "Minnesota," flag-ship North Atlantic Blockading Squadron, 1863–64; commanding steamer "A. D. Vance," North Atlantic Blockading Squadron, 1864–65; at capture of Fort Fisher, January, 1865; commanding steamer "Frolic," European Squadron, 1865–67.

Commissioned as commander, July 25, 1866; commanding apprentice-ship "Saratoga," 1868–70; special duty, New London, Conn., 1871–73.

Commissioned as captain, January 31, 1872; commanding "Brooklyn" (second-rate), South Atlantic Station, 1875–76; member Board of Inspection, 1877–80.

Promoted to commodore, July 11, 1880.

Uptake. The portion of a marine steam-boiler in which the gases of combustion, after having passed through the flues or tubes, are collected and turned upwards toward the chimney.

Uranus. In 1781, Sir William Herschel discovered what was thought to be a comet; further observation proved it to be a planet. Herschel proposed to name it Georgium Sidus in honor of the reigning king of England. Laplace proposed to call it Herschel for its discoverer. It finally received the name of Uranus, who in ancient mythology was the father of Saturn. Its mean distance from the sun is 1828 millions of miles; diameter, 36,000 miles; apparent diameter, 4″; period of revolution, 84 years. It is attended by 4 satellites at distances varying from 120,000 to 380,000 miles. Contrary to the general law, the motion of the satellites in their orbits is retrograde. Symbol ♅, the initial of Herschel, with a globe suspended from the cross-bar.

Urca. An armed Spanish fly-boat.

Ursa Major (*Lat.* "The Greater Bear"). The most brilliant constellation of the northern hemisphere, consisting of 7 principal stars. By the common people of most countries this group is called *the wagon, the great dipper*, and sometimes *the plow;* in England it has been known as *Charles's wain.* The four stars, α, β, γ, δ, form a

trapezium, the longest side of which contains α and δ, γ being in the opposite angle to α; next to δ is affixed a scalene triangle, formed by the stars ε, ζ, η, which represent the tail of the Bear. The two stars β and α are called *the pointers*, as they point to the pole star. They are 5° apart, and hence convenient to measure distances by. α *Ursæ Majoris*, Dubhe; β, Merak; γ, Phecda. The star at the bend of the handle is called Mizar; near it is a small star (Alcor), which was regarded in early days as a test of keen vision; the Arabs called it Saidak, or *the proof*. It is now easily seen.

Ursa Minor (*Lat.* "The Lesser Bear"). A constellation popularly known as *the little dipper*. It is similar in form to *Ursa Major*, the trapezium of the one being adjacent to the triangle of the other. α *Ursæ Minoris*, Polaris; β, Kochab. See POLARIS.

Usages. Besides the general laws of merchants, there are certain commercial and seafaring usages which prevail in particular countries with the force of law. Underwriters are bound by usages; and they are legal precedents binding in courts-martial.

Ushant Team (*Eng.*). The sobriquet given to that portion of the Channel fleet which blockaded Brest.

V.

V. In the log-book, *v* denotes *visibility of distant objects.*

Vacuum-gauge. An instrument for indicating the degree of vacuum, or the preponderance of the atmospheric pressure over that of the air, vapor, or gas contained within a vessel, such as the receiver of an air-pump or the condenser of a steam-engine. Like a steam- or pressure-gauge, it depends for its action upon the resilience of metal or the height of a column of mercury or water. The indications are observed either by an index on a disk, or a scale showing the varying height of a column of liquid; and the unit of measure is usually considered as one inch in height of a column of mercury.

Vacuum-pump. A pump for exhausting an air-tight chamber or reservoir of its fluid contents, leaving a vacuum within.

Vacuum-valve. A valve for admitting air or other fluid to a vacuum within a vessel or chamber, and restoring equilibrium with atmospheric pressure. The *reverse-valve* of a steam-boiler is sometimes called a *vacuum-valve.* See REVERSE-VALVE.

Vail. An old word for *lower;* as, to vail the topsails as a salute or in token of submission.

Vakka. A large canoe of the Friendly Islands.

Vallejo is situated on the northeastern shore of San Pablo Bay, at the mouth of Napa Creek, and near the west end of the Strait of Carquinez, in Solano County, Cal. It has a large and safe harbor, and is accessible to the largest sea-going ships. It has several flouring-mills, ship-yards, and shoe-factories. Large quantities of grain are shipped here. It has manufactories of steam-engines, boilers, sash, doors, etc. A U. S. navy-yard is located here, on Mare Island, for a description of which see NAVY-YARD, MARE ISLAND, CALIFORNIA. Pop. 10,000.

Valparaiso, the capital of the province of the same name, and the principal port of Chili, is situated on a large bay in the Pacific, in lat. 33° 1′ 56″ S., lon. 71° 41′ 45″ W. The Bay of Valparaiso is of a semicircular form, and capable of accommodating a very large fleet. It is well sheltered on the east, south, and west, but is entirely open toward the north; and during the prevalence of winds from this quarter in the winter season, accompanied by a heavy, rolling sea, the shipping is much exposed. The city is the greatest commercial port of the Pacific coast of South America; about 3000 vessels enter and clear the port annually, and the city has an import trade of $35,000,000, and the exports amount to $15,000,000. Pop. 98,000.

Valve. In mechanism, a contrivance for controlling the flow of confined fluids. *Automatic valves*, used in pumps, are usually made of hinged plates or of flexible material, such as leather, gum, etc., or consist of lifting disk-valves guided by spindles or vanes. These valves, which are fitted to seats having necessary openings for the passage of the fluid, yield readily to its pressure in one direction; but, by their weight or resilience, descend to their seats and prevent its reflux when the pressure ceases; *stop-valves*, or valves for regulating the flow of fluid, are so arranged as to be opened, closed, or adjusted by hand; and the *steam-* and *exhaust-valves* of engines, of which there are many varieties, are actuated by mechanism called *valve-gear*.

VALVE-CHAMBER. A chamber which contains a valve (or set of valves) with its seat, guides, and guards, and in which it performs its functions.

VALVE-GEAR. The mechanism by which the valves of a steam-engine are actuated by the main running-gear. It includes eccentrics, eccentric straps and rods, links, pins, cross-heads, rock-shafts, and arms or levers, valve-stems, etc.

VALVE-SEAT. The surface upon which a valve bears when closed, and to which it is so accurately fitted as to prevent the passage of fluid.

Van. That part of a fleet which is in front.

Vancouver, George, navigator and explorer of the northwest coast of America. Born about 1757; died May 10, 1798. Entering the navy in 1771, he accompanied Capt. Cook in his two last voyages, and in the latter part of 1780 was appointed a lieutenant; in 1790 he was made master and

commander of the "Discovery," in which ship he was sent out to ascertain if there existed in North America, between the 30th and 60th degrees of north latitude, an interior sea, or any canals of communication between the known gulfs of the Atlantic and the great sea. He sailed from England April 1, 1791, and after an examination of the Sandwich Islands, crossed, in March, 1792, to the American coast, where he received the surrender of Nootka from the Spaniards, and spent the summers of 1792–94 in surveying the coast as far north as Cook's Inlet, wintering in the Sandwich Islands. He considered his explorations to have settled the question of a northwest passage in the negative. Vancouver's Island was named by him. On his return he surveyed most of the west coast of South America from the island of Chiloe, visiting the chief Spanish settlements. He was made a post-captain in 1794, and arrived in London in November, 1795, in a state of declining health from the effects of his voyages, but devoted himself to the arrangement of his manuscripts for publication until within a short time of his death. His Voyages, edited by his brother, was printed at the expense of the government, and was shortly afterward translated into French, German, and Swedish.

Vangee. A contrivance for working the pumps of a vessel by means of a barrel and crank-breaks.

Vangs. Ropes from the end of a gaff to the side of the ship to steady the gaff.

Variables. Those parts of the sea where a steady wind is not expected.

Variation. The angle which the magnetic meridian makes with the geographical meridian. See COMPASS.

VARIATION-CHART. A chart on which is shown, by curved lines, the variation of the compass.

Veer. To pay out a rope. To wear ship. To change direction,—applied to the wind; the wind *hauls* forward and *veers* aft. It is also said to veer when it changes direction against the sun.

Vega. The star *α Lyræ*. See LYRA.

Vein. Clear water in the openings between ice-floes.

Velocity (Lat. *velox*, swift). Rate of motion. The velocity of a body is uniform when it passes through equal spaces in equal times, and variable when the spaces passed through in equal times are unequal. Velocity is purely a relative term, for there is nothing which in itself is either swift or slow, any more than great or small. The velocity of a cannon-ball appears very great, yet it is slow compared with the motion of a point on the earth's equator, carried round by the diurnal motion; and this, again, is far inferior to the velocity of the earth in its orbit, which in its turn is greatly exceeded by the velocity of light.

Initial velocity, in gunnery, is the velocity of the projectile at the muzzle of the piece; called also *muzzle velocity*.

Remaining velocity is the velocity of a projectile at any point of its flight intermediate between the piece and the point of striking.

Terminal velocity is the velocity with which the projectile strikes its object.

Final velocity is the uniform velocity with which a projectile, descending through the air, moves after the resistance of the air has become equal to the accelerating force of gravity. It is directly proportional to the product of the diameter and density of the projectile, and inversely proportional to the density of the air.

Vena Contracta. The contracted portion of a jet of fluid issuing from an orifice in a thin plate always observed at a short distance from the orifice, the effective area of which is thus reduced, at an average, to about five-eighths its actual area.

Vendace. A rare species of trout, found in Lochmaben, Dumfriesshire, Scotland; *Coregonus Willughbii.*

Vendaval. A stormy time on the coast of Mexico, in the autumn, with violent thunder, lightning, and rain.

Venice, a fortified city of Northern Italy, one of the noblest, most famous, and singular cities in the world, is built upon a crowded cluster of islets in the lagoons of the same name, on the northwest of the Adriatic Sea, in lat. 45° 25′ N., lon. 12° 20′ E. Immediately west of the island of Lido are the islands on which Venice is built, and immediately south of it is the Porto di Malamocco, now the deepest entrance to the lagoon, and the seaway for vessels of the greatest draft. Venice was for many years the first maritime and commercial power of the world. The islands upon which it is built are 80 in number, are intersected by 147 canals, and are divided into two great groups by the Grand Canal, which is about two miles long and from 160 to 230 feet broad. Many of the inhabitants are employed in fishing and in navigating vessels belonging to the port, of which there are about 30,000. The value of the imports is about $25,000,000, and exports $12,500,000. Lat. 45° 25′ 49.5″ N.; lon. 12° 21′ 8″ E. Pop. 129,000.

Vent. The aperture through which fire is communicated to the charge of a gun. An axial vent is supposed to give a slight increase of initial velocity.

VENT-DRILL. A machine for clearing the vent of a gun when choked.

VENT-PLUG. A leather stopper for the vent of a gun not in use.

Venus. When most brilliant, Venus is about 40° from the sun. When it appears in the southwest just after sunset, it is known as the *evening star*,—the Greeks called it Hesperus. When it appears in the southeast just before sunrise, it is called the *morning star*, or Lucifer. Transits of Venus across the disk of the sun are of special importance in determining the solar parallax; the next one occurs in December, 1882. Diameter, 7600 miles; mean distance from the sun, 69 millions of miles. Symbol ♀, representing a mirror.

Vera Cruz, the capital of the state of Vera Cruz, Mexico, is situated in a sandy, marshy, and unhealthy plain on the southwest shore of the Gulf of Mexico. It is defended by the strong castle of San Juan de Ulloa, built upon an island about half a mile from the shore. The harbor, a mere roadstead between the town and the castle, is very insecure, having neither good anchorage nor sufficient protection from the north winds. It is provided with a good stone mole, and on the island of San Juan de Ulloa there is a light-house, showing a brilliant revolving light,

89 feet above the sea. The trade of this city is equal to that of all the other Mexican ports combined. The chief exports are the precious metals, cochineal, sugar, flour, indigo, provisions, leather, vanilla, soap, logwood, and pimento. Lat. 19° 11′ 54″ N.; lon. 96° 8′ 36″ W. Pop. 16,000.

Veritas. A register of shipping established in Paris, on the principle of Lloyd's List. See CLASSIFICATION.

Vernal Equinoctial Point. The first point of Aries. See EQUINOCTIAL POINT.

Vernal Equinox. See EQUINOX.

Vernier. A small graduated scale for the measurement of minute divisions on the limb of a sextant, scale of a barometer, etc.

Vertical Circles. Great circles of the sphere intercepting each other in the zenith and nadir, and cutting the horizon at right angles.

Vespucci, Amerigo, was born at Florence, March 9, 1451. His first voyage was in the expedition commanded by Admiral Hojeda, which sailed from Cadiz, May 20, 1499. The continent of America received its name from this navigator in virtue of his having sailed along the coast, and being the first to publish an account of the New World. But the discovery by Columbus was anterior to the voyage of Vespucci. Upon his return to Europe he was sent to Brazil, and after this his voyages were unimportant. He died at Seville, February 22, 1512.

Vessel. A general name for all the different sorts of ships, boats, etc., navigated on the ocean or on rivers and canals.

Vessels, Title to. The title to a vessel rests in an instrument in writing, in the nature of a bill of sale, which is required by law to be duly acknowledged before a notary public, or other officer authorized to take acknowledgment of deeds. This instrument, as well also as every mortgage, hypothecation, or conveyance of any vessel, or part of any vessel, must be recorded in the office of the collector of customs where such vessel is registered or enrolled; and without such record no bill of sale, mortgage, hypothecation, or conveyance, is valid against any person other than the grantor or mortgagor, his heirs and devisees, and persons having actual notice thereof. It is made the duty of the collector to record all such bills of sale, mortgages, hypothecations, or conveyances, and also all certificates for discharging and canceling any such conveyances, in books kept for that purpose, in the order of their reception; noting in such books, and also on the instrument itself, the time when the same is received, and to certify on the bill of sale, mortgage, hypothecation, or conveyance, or certificate of discharge, or cancellation, the number of the book and page where the same is recorded. All bills of sale of vessels registered or enrolled are required to set forth the part of the vessel owned by each person selling, and the part conveyed to each person purchasing. See Revised Statutes U. S., Sections 4192, 4193, 4196.

Via Lactea. See GALAXY.

Vice-Admiral. See ADMIRAL.

Victualer. A vessel which carries provisions. In early days each man-of-war had a victualer especially attached to her; as, in Henry VIII.'s reign, we find the "Nicholas Draper," of 140 tons and 40 men, was victualer to the "Trinity Sovereign"; the "Barbara" of Greenwich to the "Gabriel Royal," and so on.

Vi et Armis. By force of arms.

Vigia. A hydrographical warning on a chart, to denote that the pinnacle of a rock, or a shoal, may exist thereabout.

Villeneuve, Peter Charles John Baptist Sylvester de, a French vice-admiral, was born at Valensoles in 1763, and died at Rennes in 1806. He entered the navy in 1778, and had attained the rank of *capitaine de vaisseau* when the French Revolution occurred. He was made a rear-admiral in 1796, and ordered to take part in the Irish expedition, but failed to do so, on account of adverse winds detaining the vessels of his squadron. In the Egyptian expedition he had a command, and was in charge of a division of the French fleet at the battle of Aboukir, and came out of that terrible action with four vessels, which he succeeded in taking to Malta.

In 1801, Napoleon, being then first consul, placed him in command of Martinique, and in 1804 promoted him to be vice-admiral, intending to place him in charge of the naval forces during the contemplated descent upon the English shores, for which such extensive preparations were making at Boulogne and elsewhere. The plan was for Villeneuve and his fleet, in combination with the Spanish fleet, under Admiral Gravina, to sail for the West Indies, as if to operate against the British possessions there, and thus to draw off the bulk of the British fleet in pursuit. He was then quickly and secretly to return to Europe, enter the Channel, and there find the rest of the French fleet concentrated to protect the crossing of the army, while the English were searching for him in far distant seas. Villeneuve sailed from Toulon in January, 1805, with 28 sail of the line, but put back on account of bad weather, and by delay disarranged plans which depended upon too many contingencies. He did not join Gravina at Cadiz until April 9, at least two months later than the arrangements called for. With the combined fleet he then sailed for the West Indies, where he took Fort Diamond, and captured a valuable convoy. During this time Nelson, who was ignorant of his destination, was scouring the Mediterranean in search of him, but came back from Egypt to Naples, no wiser than he went. At last he got upon Villeneuve's track, followed him, and was reported at Barbadoes. The French admiral, having drawn the English fleet to a great distance, then hastened to return to Europe. He captured on the passage a most valuable prize in a privateer with a rich lading of specie captured from the Spaniards, but unfortunately he was detained by bad weather, and was 42 days between the Azores and the Continent. Off Cape Finistère his fleet encountered that commanded by Sir Robert Calder, consisting of 19 vessels, and an engagement followed, which was by no means decisive, and the inferior English fleet withdrew, after inflicting much damage upon that of the allies. This equivocal victory irritated Napoleon exceedingly, and he caused a note to be printed in the *Moniteur*, which may be rendered as follows:

"If we can some day find a man combining character, courage, coolness, and audacity, the world will see what our sailors are capable of accomplishing."

This severe reflection upon Villeneuve was caused by his delay interfering so seriously with Napoleon's plans, who did not consider that he could not control the weather, and who resented fiercely Villeneuve's failure to destroy or capture Calder's squadron. It was not yet too late for the invasion to have taken place, if the combined fleet had made for Brest; but Villeneuve saw fit to go into Cadiz, where Nelson, who had returned from his fruitless cruise, at once blockaded him, and Bonaparte was obliged to give up his cherished plan, especially as the state of affairs in Austria forced him to give his personal attention in that direction. Villeneuve, deeply mortified by Bonaparte's reprimand, determined to re-establish himself in the emperor's favor by a brilliant and decisive action with the English fleet. Alluding to the note in the *Moniteur*, he wrote to the Minister of Marine: "If it be true that nothing but firmness and audacity are needful, I will leave nothing to be desired on that score the first time that I go to sea."

He was, indeed, at that time making up his mind to measure forces with his great adversary, Nelson. Villeneuve finally sailed from Cadiz on the 21st of October, with 33 ships of the line, French and Spanish. The English fleet had the same number, but some preponderance in weight of metal, and a great advantage in discipline and ability to manœuvre. The plan of battle which the French admiral had laid down was rendered nugatory by the audacious movements of Nelson, who, at the very outset, broke the French line, and fought the two wings separately. It was Napoleonic strategy applied to a sea-fight. The whole world knows the story. Villeneuve, in the "Bucentaur," was soon overmatched and captured, and the French navy received that day a blow from which it was many a year in recovering, while the English lost Nelson.

Napoleon heard of the disaster while in the midst of his own successes in Germany, and never pardoned Villeneuve. The latter, when liberated by the English, in April, 1806, returned to France, in hopes of justifying himself. He wrote to Paris, and then followed his letter, but received the answer of the Minister of Marine while on the road, which answer so overwhelmed him with mortification that he stabbed himself through the heart with a dagger.—*E. Shippen.*

Viol, or Voyol. A large messenger formerly used to assist in weighing an anchor by the capstan.

VIOL-, or VOYOL-BLOCK. A large single-sheaved block through which the messenger passed when the anchor was weighed by the fore or jeer capstan.

Virgiliæ. A denomination of the Pleiades.

Virgo, Constellation of (*Lat.* "The Virgin"). The sixth constellation of the ancient zodiac, lying between Leo and Libra. It contains a very brilliant star, *α Virginis*, called also *Spica*, which may be found by drawing a line from *Dubhe* through *Cor Caroli*, and producing it to a little more than the same distance; or it may be recognized as forming an equilateral triangle with Arcturus and β Leonis (Denebola), of which it is the southern angle.

Virgo, Sign of. The sixth sign of the ecliptic, including from 150° to 180° of longitude. Owing to the precession of the equinoxes, the *constellation* Virgo is no longer in the *sign* of this name, the constellation Leo having taken its place. The sun is in Virgo from about August 23 to about September 23. Symbol ♍.

Visible Horizon. See HORIZON.

Vis-viva. The product of the *mass* of a body multiplied by the *square of its velocity*. It is double the *actual energy* of the body, which is its *weight* multiplied by the square of its velocity and divided by $2g$. Expressed in formula, the notation of which is evident, $\frac{m v^2}{2} = \frac{W v^2}{2g}$.

Vitry. A kind of light, durable canvas.

Vivier. A French fishing-boat having a well amidships in which to keep the fish alive until arrival in port.

Vizy, or Vize. An old name for the muzzle-sight on a musket.

Voes. Arms or inlets of the sea, or sounds, in the Shetland and Orkney Isles. Also applied to creeks and bays.

Vogovans. From *voguer* and *avant*, chief rowers in the galleys.

Volans. See CONSTELLATION.

Volley. The simultaneous discharge of a number of fire-arms.

Volligue. A small boat used on the shores of Asia Minor.

Voluntary Stranding. The beaching or running a vessel purposely aground to escape greater danger; this act is treated as particular average loss, and not a damage to be made good by general contribution.

Voucher. A written document upon which any public account or charge is established.

Voyage. A journey by water, including both the outward and homeward voyages.

Vrach. Sea-weed used as fertilizing material.

Vulfe. A rapid whirlpool or race on the coast of Norway.

Vulgar Establishment of the Port. See TIDE.

Vulpecula. See CONSTELLATION.

W.

W. Abbreviation for *word* in the U. S. General Service Signal Code. In the log-book, *w* indicates *wet dew*.

Wad. A plug of hay, junk, etc., fitted to the bore of a gun, and placed over the shot in loading to keep it in place. *Grommet-wads* are simply rope grommets. *Junk-wads* are made of coiled junk. *Selvagee-wads* are made of rope-yarns, coiled up selvagee-fashion, and are only used with round shot.

WAD-HOOK. A worm (which see).

Wadmarel (*Eng.*). Coarse hairy cloth, used formerly in making pea-jackets.

Waffle-powder. A large-grained powder, designed by Commodore Jeffers.

Waft, Weft, or Wheft. A flag knotted or stopped in the middle is said to have a waft in it. This is a signal, used at the staff or half-way up to the gaff to show that a man is overboard; at the peak, a desire to communicate; at the mast-head, to recall boats, etc.

Wafter. A passage-boat.

Waftors (*Eng.*). Blunted swords for exercise. Certain officers appointed to guard the coast fisheries.

Wagering-policy, or Wager-policy. An insurance policy where there is no interest in ship or cargo. A kind of wager on the performance of the voyage.

Waggel. The young of the black-backed gull, *Larus marinus*.

Waghorn, Thomas. The feasibility of reviving a communication between Europe and India *via* the Red Sea having been established, this enterprising Bengal pilot took the lead in practically showing how much economy in time might be effected by the formation of a company that could equip steamers for the conveyance of mails and passengers to and fro. His scheme was carried out by an enterprising association, bringing Bengal 10,000 miles nearer to London. He was made a lieutenant in the royal navy, and received other rewards.

Waif. Derelict goods; goods not claimed.

Waist. That part of the ship between the quarter-deck and forecastle.

WAIST-ANCHOR. The anchor stowed in the waist; the sheet-anchor.

WAIST-BOARDS. Boards put in the waist to prevent the water from coming on board, especially in the gangways.

WAIST-BOAT. A boat carried in the waist.

WAIST-BLOCKS. *Chess-trees* in the waist.

WAIST-CLOTHS. The hammock cloths of the waist-nettings.

WAISTERS. Landsmen and worn-out seamen formerly stationed in the waist.

WAIST-NETTINGS. The boxes on the rail in the waist, in which hammocks are stowed.

WAIST-RAIL. The molding-rail in the waist.

WAIST-TREE. See ROUGH-TREE.

Wale-knot. A wall-knot.

Wales. *Main wales* are the strakes from the lower port-sill of the gun-deck to the bottom plank. *Channel-wales*, sometimes called strings, are those strakes between the spar- and main-deck ports in ships of three decks, and spar-deck ports in those of two decks. Middle wales are placed between the main- and gun-deck ports in ships of three decks.

WALE-PIECE. A piece of timber bolted horizontally along a dock, about the height of the wales of a ship, to serve as a fender.

WALE-REARED. Wall-sided.

Wales, Philip S., Surgeon-General U.S.N. Born February 27, 1837, in Annapolis, Md. After graduation at the University of Maryland, and a course of study in the Medical Department of the University of Pennsylvania, he settled at Baltimore, Md., whence he removed first to Philadelphia, Pa., and afterwards to Washington, D. C. Appointed assistant surgeon August 7, 1856; Naval Academy, 1857; steam-frigate "Mississippi," East India Squadron, 1858–60; steamer "Water-Witch," 1861. Commissioned as surgeon, October 12, 1861; naval hospital, Norfolk, 1863; steamer "Fort Jackson," North Atlantic Blockading Squadron, 1864, and same vessel, West Gulf Blockading Squadron, 1865; Examining Board, 1868; sloop "Portsmouth," South Atlantic Squadron, 1868–69; steam-sloop "Guerriere," European Station, 1870–72; member Board of Examiners, 1872–74. Commissioned as medical inspector, June 30, 1873; special duty, Washington, 1874–79. Surgeon-general and chief of the Bureau of Medicine and Surgery, with relative rank of commodore, January 26, 1880.

Surgeon-General Wales is a member of the Academy of Natural Sciences, the American Medical Association, and the Gynæcological Society of Boston. His contributions to medical literature comprise "Surgical Operations and Appliances," "A New Method of Controlling the Velum Palati," "A New Rectal Dilator and Explorer"; papers in the *American Journal of Medical Sciences* on "Cerebro-Spinal Meningitis," "Amputation of Shoulder-Joint," "Fracture of Lower Jaw," "Gunshot Wound of Stomach," "Ligature of the Femoral Artery," "Fracture of Thyroid Cartilage," "Operation for Hydropthalmia," and "Aneurism of the Heart"; a series of papers in the *Philadelphia Medical and Surgical Reporter* on "Instrumental Diagnosis," with a paper entitled "Description of a New Endoscope"; a paper in the *New York Medical Record* on "Traumatic Tetanus," and numerous reviews in various medical journals.

Walke, Henry, Rear-Admiral U.S.N. Born in Virginia, Princess Ann County, on Lyn

Haven River, Dec. 24, 1808. Appointed midshipman from Ohio, February 1, 1827; attached to receiving-ship "Alert," Norfolk, March 27, 1827; attached to "Natchez," West Indies, July, 1827; "Ontario," Mediterranean Station, February 8, 1829; frigate "Constellation," June 5, 1829; detached, November 16, 1831; Naval School at Norfolk, 1831–33.

Promoted to passed midshipman, June 10, 1833; "North Carolina," Pacific Station, November, 1836, to July, 1839; same ship in New York until October 5, 1840; "Boston," East Indies and around the world to August 8, 1843; brig "Bainbridge," Brazil, May 18, 1844, to September 17, 1845; bomb-brig "Vesuvius," West Indies, 1847; present at the surrender of Vera Cruz, Tabasco, Tuspan, and Alvarado; transferred to frigate "Mississippi"; frigate "Cumberland," Mediterranean Squadron, 1849–51.

Promoted to commander, Sept. 14, 1855; commanded the "Supply," coast of Africa, 1858–59, and in the West Indies, 1859–60. In the beginning of the Rebellion Commander Walke rendered most important service in preventing the capture of Fort Pickens by the Confederates, which enabled our forces ultimately to recapture the navy-yard, Forts Barrancas and McCrea, and Pensacola, with all that section of the State of Florida which borders on those extensive inland bays. He also rescued all our loyal officers, sailors, marines, and government employés from want and imprisonment. This service was performed under extraordinary difficulties and unusual circumstances, which compelled him to act contrary to the orders of the commodores on that station and the Secretary of the Navy; this conduct, although highly approved by all fair-minded officers, was censured by the Secretary of the Navy. The late Board of Rear-Admirals reported that it was especially struck with this highly creditable and meritorious conduct, and that it had a marked and important bearing on the success of our arms. Commander Walke was the senior naval officer present when this service was performed. Steamer "Mount Vernon," May 14, 1861; ordered as light-house inspector of 11th district, September 6, 1861, but orders changed to Mississippi Flotilla, September 6, 1861; commanded gunboat "Taylor," September 12, 1861, at Cairo, Ill.; commanded gunboats at the battle of Belmont, Nov. 7, 1861, and protected the army under Gen. Grant, and prevented the Confederate army from cutting off a portion of our troops on their retreat to the transports, for which he was highly commended in the general's report of the battle; commanded gunboat "Carondelet," 13 guns, partly ironclad, at the battle of Fort Henry, February 6, 1862,—the first decisive victory over the enemy's fortifications in the Western waters, for which Flag-Officer Foote and all his officers received the thanks of the Secretary of the Navy, of Congress, and of the State of Ohio; commanded the "Carondelet" at the battle of Fort Donelson, on the 13th, 14th, and 16th of February, 1862; commenced the battle alone on the 13th, and on the 14th held his position in the front line of battle in the general engagement, being the last to retire; the "Carondelet" was thrice as long under fire as any other gunboat in this battle of two days, and her loss in officers and men greatly exceeded that of all the rest of the flotilla; commanded the "Carondelet" at the bombardment of Island No. 10, March 17, 1862, and voluntarily ran the gauntlet of the enemy's batteries—April 4, 1862—with the "Carondelet" alone, being the first example of successfully passing the enemy's batteries and attacking them in the rear on the Mississippi, and finally captured the enemy's batteries below the island on the 6th and 7th (with but little assistance), without which no further attempt would have been made to capture or pass that island by our army and navy. This action was then considered the most important victory and meritorious achievement of the war, as it broke the blockade of the enemy's line of fortifications without the loss of a man on our side. The Secretary of the Navy referring to it wrote, "It was a daring and heroic act, well executed, and deserving a special recognition. These fearless acts dismayed the enemy, and eventuated in the surrender to yourself of Island No. 10; and that a nation's thanks were due, etc." These statements of the Secretary of the Navy were approved and indorsed by Flag-Officer Foote. May 11, 1862, Commander Walke led our fleet at the battle of Fort Pillow, with the first division of the flotilla attacked the enemy and rescued the gunboat "Cincinnati," the "Carondelet" being the first, or one of the first in, and the last out of the battle, and much longer under fire at close quarters than the rest of the fleet, and she remained alone in possession of the battle-field. In the battle of Memphis, June 6, 1872, the "Carondelet," under his command, was second in the line of battle with the flag-steamer when the fleet captured that of the enemy (except one gunboat and two which were sunk), with several of their largest steamers, also the navy-yard and all their public property, with the city of Memphis. The "Carondelet," still under his command, was the principal gunboat that engaged the famous Confederate ram "Arkansas," which was greatly her superior in size and strength, and after a well-contested battle the latter relinquished the contest, with the loss in killed and wounded greatly exceeding that of the "Carondelet."

Commissioned as a captain, July 16, 1862; commanded the ram "Lafayette" (partly clad with 1-inch iron); passed the batteries at Vicksburg, April 16, 1863, with the Mississippi Flotilla, under Rear-Admiral Porter. At the battle of Grand Gulf, April 29, 1863, he led the second division of our fleet, which, with the first, nearly silenced all the enemy's batteries at close quarters, being under fire more than 5 hours, when the fleet was withdrawn, and he was ordered back to silence the main fort, on the Point of Rocks, with the "Lafayette" alone, which he did in about 25 minutes. Having passed these forts three times under close fire, and having made the last attack upon them alone the day before they were evacuated, the "Lafayette" was under fire with that formidable chain of heavy batteries 8 or 9 hours, and much longer than the rest of the fleet, without the loss of any of her officers or crew, and but one officer slightly wounded, this being the seventh desperate and victorious battle, in which there was but 1 killed and 2 wounded under the command of Capt. Walke, whose vessels were always as much and generally more exposed to the fire of the enemy's guns, and as frequently struck by their

shot and shell at close quarters as any gunboat of the flotilla. And it is worthy of record that his officers and crew were always required to "remember to keep holy the Sabbath-day," according to our naval regulations. He dispersed the Confederates under Gen. Taylor at Simmsport, La.; blockaded the mouth of the Red River, June 4, 1863; ordered to the command of the steamer "Fort Jackson," July 24, 1863. Capt. Walke was the leader and one of the principal actors in all the above-mentioned actions, and for one or two of these Rear-Admirals Foote, Davis, and Porter were thanked and promoted. September 24, 1863, to August 22, 1865, he commanded the "Sacramento" on special service in search of the "Alabama," and was close on her track when she was sunk by the "Kearsarge." He blockaded the Confederate steamer "Rappahannock" at Calais, France, until the end of the war, and intercepted her when she escaped into British waters under British colors.

Commissioned as commodore, July 25, 1866; commanded the Naval Station at Mound City, Ill., May 1, 1868, to November, 1869.

Promoted rear-admiral, July 13, 1870. Retired voluntarily, April 26, 1871; member Light-House Board, 1871–72. Rear-Admiral Walke's services were equal, if not superior, to those of any other officer of the navy with the forces under his command.

Wall-knot. See Knot.

Wall-piece. An old heavy musket.

Wall-sided. Having sides nearly perpendicular.

Walrus. An aquatic mammal, the *Trichechus rosmarus*, allied to the seals, with long canine teeth. Its flesh is good for food, and its skin and tusks are valuable.

Walt (*Eng.*). An old word for crank, or tottering.

Walty. Crank.

Wane (*Eng.*). Deficiency in timber; want of squareness at the corners.

Wane-cloud. Cirro-stratus.

Wangan. A provision-boat, used in Maine.

Wany. Tapering or uneven; spoiled by wet, as timber.

Wapp, or Whap. Formerly, any short pendant or thimble, through which running rigging was rove. A rope connecting the shroud to the laniard; a kind of stopper for the shroud with wall-knots in it.

War-caperer. A privateer.

Wardroom. The apartments of the commissioned officers, including mess- and state-rooms. It is on the berth-deck of frigates and sloops, but was on the gun-deck of line-of-battle ships.

Wardroom-country. The open space between the state-rooms in the wardroom.

Wardroom-officers. Commissioned officers messing in the wardroom. All commissioned officers in the U. S. navy are wardroom-officers, except those ranking with ensign. When an ensign, or an officer having the equivalent rank, is a watch-officer or the head of a department, he is a wardroom-officer.

Ware. See Wear.

Warehousing. Placing goods in bonded warehouses until cleared.

Warm-sided. Mounting many heavy guns.

Warner (*Eng.*). A beacon, buoy, light, etc., to warn vessels of dangers. A sentinel formerly placed on heights to give notice of the approach of vessels.

Warning-lights. Flash-lights, burned in case of emergency, to warn vessels of danger, etc.

Warning-signal (*Eng.*). A signal hoisted to warn vessels not to cross a bar. A storm-signal.

Warp. A tow-rope or light hawser, used to move a ship about. (*Eng.*) A term for four herrings. Land between sea-banks and the sea. A given length of rope, rope-yarns, etc. The threads along the length of canvas. *Shroud-warp*, the length from which shrouds are to be cut. *To warp*, to move a vessel with warps, or lines, fast to fixed points. To stretch rope-yarns into fixed lengths for tarring. (*Eng.*) To flood land near rivers.

Warpage. A charge per ton for warping ships.

Warping-block. A large block used in making warps in rope-walks.

Warping-chock. A large chock placed in a port to lead hawsers through, in warping.

Warping-hook. A hook used by rope-makers for hanging the rope on, in warping yarns.

Warping-post. A strong post in a rope-walk, used in warping yarns.

Warrant. An instrument conferring authority upon persons, inferior to a *commission*. A writ issued by an inferior power, as by the Secretary of the Navy. A document assembling a court-martial, court of inquiry, etc. *Dock-warrant*, a custom-house license or authority. *Press-warrant*, a warrant formerly issued giving power to press seamen. *Brown-paper warrants* (*Eng.*), those given by a captain, and revokable by him. *Acting warrant*, a warrant given by a commander-in-chief, or by the Secretary, to a person temporarily chosen to fill a warrant office.

Warrant-officer. An officer holding his position by virtue of a warrant issued by some power inferior to the supreme magistrate, as by a navy board, the Secretary of the Navy, etc. *Warrant-officers* are selected or promoted from seamen, ship-carpenters, etc., and comprise the boatswain, gunner, carpenter, and sailmaker. They receive at sea, in the U. S. navy, from 1200 to 1800 dollars per year, according to length of service. They rank next below mates, and are quartered and messed separately. Formerly their rooms were forward, and they were then called *forward officers*, but this name is no longer used.

Warranty. A contract or clause in marine insurance policies, engaging that certain things affecting the risk shall be done, or shall exist, etc. Certain warranties are implied in all instruments.

Warren, Sir J. Borlase. After a lengthened service in a subordinate grade, this excellent officer was fortunate enough to capture a French line-of-battle ship and 3 frigates, and thus gained promotion to the rank of admiral. In 1812, during the war between England and the United States, Sir J. B. Warren was employed on the eastern coast of America, and likewise visited the West India Islands.

Warren-head (*Eng.*). A dam across a river.

War-ship, or War-vessel. A vessel built to engage in war; a national ship, armed and equipped for war.

Warth (*Eng.*). A ford.

Wash. Accumulated silt in river mouths.

Flooded banks or sands. A shallow inlet or gulf. The blade of an oar. (*Eng.*) A Billingsgate oyster-measure, two-thirds of a bushel. *Awash*, even with the water's edge.

Wash-board, or Wash-strake. Broad, thin plank fastened on the gunwale of a boat or small vessel, to keep the spray out. Boards fitted to the sills of lower-deck ports of a liner. The white facings of old naval uniforms.

Wash-clothes. The clothes that have been washed and hung on the clothes-lines to dry.

Wash-deck Gear. The brooms, squilgees, holy-stones, buckets, etc., used in washing decks.

Washer. A ring or plate of metal, leather, gum, or other material suitable to the purpose intended, placed under a bolt-head or nut, either for distributing the strain of the bolt over a greater area than that of the face of the nut, relieving the friction of turning the nut, or rendering the junction tight. A loose ring placed between the hub of a wheel or gun-truck and the linchpin. A ring of leather or gum placed between hose-couplings to prevent leakage.

Washington, the capital of the United States, is finely located on the Potomac River, in the District of Columbia. Lat. (of Observatory) 38° 53′ 9″ N., lon. 77° 2′ 48″ W., from Greenwich. That portion of the American ephemeris which is designed exclusively for astronomical use, is adapted to the meridian of Washington, and American maps are frequently constructed with this meridian as the origin whence longitudes are reckoned. The city is situated between two small tributaries of the Potomac, the one on the east called the East Branch, and the one on the west called Rock Creek. In addition to its being the seat of the national government, and containing all the Department buildings, it is also the seat of the U. S. Naval Observatory, one of the institutions most creditable to the government, occupying a commanding site on the banks of the Potomac southwest of the President's mansion. The arsenal on Greenleaf's Point, at the junction of the East Branch with the Potomac, is one of the principal establishments of its kind in the United States. About 1¼ miles northeast from the arsenal on the East Branch is the navy-yard. (See Navy-Yard, Washington, D. C.) The government asylum for insane soldiers and sailors, and the Soldiers' Home for disabled soldiers, are also located here. Pop. 160,000.

Wash-water (*Eng.*). A ford.

Waste. Material which cannot be utilized for the purpose for which it was intended. *Cotton-waste* is the portion of yarn that will not unwind from the bobbins of cotton machinery. It is used for wiping oil and dirt from machinery, to which purpose it is better adapted than any other substance.

Waste-board. See Wash-board.

Waste-steam. Steam that escapes from the safety-valve of a steam-boiler, or leaks through the joints, valves, or pistons of a steam-engine.

Waste-steam Pipe. A pipe for conducting superfluous steam from a steam-boiler or other apparatus to some convenient point.

Waste-water Pipe. A pipe for discharging superfluous water from a reservoir of any kind.

Watch. The part of a ship's company that work her for an allotted time. The crew is generally divided into the starboard and port watches, but it may also be divided into three watches, as is at times customary with the firemen. The watch are not required to keep their feet, or even to keep awake, but must be ready for a call, and cannot go below-decks. They are mustered at the beginning of, and often during, the watch, by a midshipman, or other junior officer, or by the captains of the parts of the ship. Both watches, or *all hands*, are called at any time in a sudden emergency, when the executive-officer takes charge of them. The watch is *set* at 8 o'clock each evening, and the relief watch is called generally ten minutes before 12, 4, etc. The watches go to meals separately, except in fair weather, under steam alone, when both may go. With each watch is a boatswain's mates, one or two quarter-masters, one or two quarter-gunners, a carpenter's mate, and a ship's corporal. The marines are also watched, in connection with their sentry-duty, and assist in working ship. The officers of the line (and engineers when steaming) are also divided into watches, and the lieutenants have charge of the watch, the midshipmen and mates being junior officers, stationed on the forecastle or quarter-deck. The first and second lieutenants, and staff-officers, warrant-officers, many petty officers, cooks, stewards, etc., are not watched, and mechanics, etc., are only watched at night. *Watch and watch*, the usual arrangement in two watches, alternating in duty. *Anchor-watch*, a detail of men, or a quarter-watch kept when the ship is at single anchor. *Quarter-watch*, one-fourth the working hands,—half of each watch. The watch is divided into first and second parts, and these comprise the quarter-watches. *To relieve the watch*, to formally shift watches, after the new watch is on deck.

The length of time into which the day is divided, or the time one watch remains on deck. *First watch*, from 8 P.M. till midnight. *Middle-watch*, or *mid-watch*, from midnight until 4 A.M. *Morning-watch*, from 4 to 8 A.M. *Forenoon-watch*, from 8 to 12 M. *Afternoon-watch*, from 12 M. to 4 P.M. *Dog-watches*, two watches of two hours' length: *first dog*, from 4 to 6 P.M.; *second dog*, from 6 to 8 P.M. These are necessary for shifting the two watches, so as to give each a turn of 8 hours below at night. There are no dog-watches in the French service, and instead, there are two 6-hour watches. *Port- or harbor-watch*, an arrangement of the officers' watches, by which, when in port, two remain on duty at a time, alternating the watches. By the usual arrangement of the officers' watches at sea, they follow each other in succession. A buoy *watches* when it floats properly on the surface. *Watch ho, watch!* a warning-cry used in heaving the deep-sea lead, to indicate that the line is running out, and to warn the next person holding it. *To watch a smooth*, to look out for a smooth sea before putting the helm down. *To watch the crew*, to arrange them in watches.

Watch-bell. A small bell sometimes used in night-watches instead of the larger ship's bell.

Watch-bill. The list of the crew divided into watches. It is generally in connection with the quarter-bill and the station-bill. See Watch-, Quarter-, and Station-bill.

Watch-glass. A half-hour glass, formerly used to indicate time during the watches.

Watch-gun. A gun sometimes fired at 8 o'clock, on *setting* the watch.

Watch-officer. From three to five officers, of the grade of lieutenant-commander, lieutenant, master, or ensign, are ordered to each vessel as watch-officers. Lieutenant-commanders have been seldom assigned to this duty since the reduction in the number of officers in that grade, and ensigns are sent to the smallest vessels only.

The watch-officer, while on duty, is the representative of the commanding officer, and his authority is subject only to that of the commanding and executive-officers. He executes all orders received from the commanding and executive-officers, and must conform, in his manner of carrying on duty, to the regulations and to the customs of the service.

On taking charge of the deck, he informs himself of the position of the ship in regard to all dangers, as shoals, rocks, land, other vessels, etc. Throughout his watch he pays strict attention to the steering and logging, and is careful to insert in the log-book the various facts and data required by the instructions in the regulations. He reports to the commanding officer all facts of special interest, such as the making of land, or of a sail or light. He should never, on his own authority, carry sail beyond the limits of prudence. He sees that the etiquette of the quarter-deck is observed, attends all commissioned officers as they leave the ship, and receives them when they come on board. During his watch he is responsible for the proper management of the ship under all circumstances, and for the discipline of the crew. On his judgment frequently depends the safety of the ship, and he should, therefore, be prepared to meet any emergency that may arise, such as a squall, fire, collision, etc.

An officer's value is better shown in avoiding difficulties than in extricating himself from them. If the subordinate officers and look-outs are kept on the alert, and the instructions concerning the running-lights, fog-signals, etc., are strictly enforced, collisions will be of rare occurrence. If the corporal of the guard and master-at-arms are thorough in their inspections, a fire can make but little headway before discovered.

And so in regard to emergencies in general, it may be observed that they can be avoided ordinarily by timely precautions. In case an emergency does occur, there are two qualities which are necessary to an officer to carry him through creditably,—*i.e.*, *coolness* and *common sense*. Common sense cannot be acquired,—it is a natural gift. Coolness is born of confidence, and confidence is inspired by experience; of this latter article, the watch-officer of to-day is likely to have a surfeit.

Watch-, Quarter-, and Station-bill. Bills or lists of the crew, with their stations, etc., at guns and on the yards, prepared by the executive-officer, and posted so that the crew may see them. The bills in the U. S. navy are now uniform for all ships, and consist of several parts. A general description of the vessel and of her engines is first given. Next a description of her battery, of the capacity of magazines, shell-rooms, and of the powder-tanks, and the number of small-arms. A diagram of the vessel follows, then a description of the boats, of the life-rafts, life-preservers, pumps and hose, and of the capacity of the water-tanks. The dimensions of spars and the sail-areas follow, then the anchors, chains and hawsers, and the spare spars and sails. A list of the officers, the complement of the crew, and the force-bill terminate this preliminary portion.

Next comes the *watch-bill*. The crew are divided into several parts, aside from the main division into two watches, viz., forecastle, foretop, main-top, mizzen-top, and after-guard, each consisting of first and second parts, and petty officers, watched messengers, idlers, mechanics, engineer's force, marines, and bandsmen. Each man's name is written, with his rate or rank, opposite a number, odd numbers in the starboard, even in the port watch, beginning with 1, and opposite his name is also written, in appropriate columns, his gun or division, boat, company, mess, and his station at loosing and furling sails. The *engineer's watch-bill* gives a list of the men, their watch- and engine-room numbers, and their rates. The watch-bill is terminated by a description of the manner of stowing hammocks, and diagrams of the decks, showing the berthing arrangements.

Then follows the *quarter-bill*. This gives a list of the men, with their watch-numbers, rates, ship's- or paymaster's-numbers, gun-numbers, and stations at the guns, together with the quarter-gunners and officers of divisions. From 3 to 5 guns constitute a division, and sometimes a pivot-gun on the upper deck is in a division by itself. Following the gun-division are the navigators' division, comprising those men who work and steer the ship during action, the powder-division, to furnish powder, shot, and shell to the guns, the marine-guard, and the surgeon's and the paymaster's divisions. A list is then given of the boarders, of the riflemen, of the firemen, pumpmen, and sail-trimmers. A list of stations at torpedo-exercise and the fire-bill follow, and terminate the quarter-bill. A list is then given of the life-boats' crews, detailing them, with their duties, in each watch. Then follow the boats' crews, both for ordinary work and for equipping for action, and with the station of each person in abandoning the ship, in case of wreck. Each man's duty, and the articles he shall furnish in providing the boat, are prescribed. The battalion organization then follows, giving each company and howitzer crew, with its place in the battalion.

The concluding portion of the book is the *station-bill*, giving the officers' stations, diagrams of the spars, with the position of each looser and furler, and the detailed station of each man in the crew for the various evolutions of loosing sail, furling sail, bending sail, sending up and down light yards, housing and fidding topmasts, sending up and down topsail-yards and lower-yards, hoisting out and in boats, mooring and unmooring, making sail and getting under way, setting and taking in stun'-sails, tacking and wearing, reefing topsails and courses, shortening sail and anchoring, manning yards and clearing ship for action. The *combination-bill* shows the duties of each one of the crew in all these evolutions at a glance. Details are then given for preparing ship for sea, cleaning ship, spreading and furling awnings, and stopping on scrubbed hammocks. The routines of divisional exercises, and of spar- and sail-drills for each day, and a monthly, half-monthly, and daily routine, complete the bills. See Routine.

Watchet (*Eng.*). Light blue cloth formerly worn by sailors.

Watch-tackle. See TACKLE.

Water. The drinking water for use on shipboard was formerly kept in casks, stowed in several tiers, the lowest being the *ground-*, the others the *riding-tiers.* More recently, iron tanks, fitted to the form of the ship, and placed in the hold, have been used. Later, iron ships have had hollow masts, so that water may be carried in them. Fresh water is now distilled from *sea-water*, by distilling apparatus, in steamers, and in some sailing-vessels, and thus purer water is insured. One ton of coal should distill 7 tons of fresh water. Each man is allowed 1 gallon of water per diem. Water, before being received on board, must be tested by the medical officer, for impurities, and should not be received until passed by him. Fresh water is only used on shipboard for drinking and culinary purposes, by the crew, and occasionally, paint-work is scrubbed with fresh water. *To make water*, to leak. *To water ship*, to take a supply of water on board. This is done by filling the large casks, and emptying them afterwards, by filling the launch in fresh water and towing her off, or through the medium of a *water-boat*, or hydrant.

WATER-ANCHOR. See SEA-ANCHOR.

WATER-BAILIFF (*Eng.*). An officer who searches vessels for suspected persons and goods, etc.

WATER-BALLAST. Water used to ballast a ship or boat. When the tanks are emptied of fresh water, it is sometimes necessary to let salt water run into them, to be used as ballast. Some English colliers have large tanks below the coal-bunkers, to be filled when the latter are emptied, with salt water, as ballast.

WATER-BARK. A Danish water-boat.

WATER-BATTERY. A battery nearly on a level with the water.

WATER-BEWITCHED DRINKS (*Eng.*). Tea, *geograffy*, 5-water grog, and other diluted drinks.

WATER-BOARD. A board set up to windward in a boat to keep the water out.

WATER-BOAT. A boat containing a large tank, filled with fresh water, and having steam- or hand-pumps for conveying it into ships. A boat filled with water in bulk or in casks, for ship's use.

WATER-BORNE. Floating on the water. A ship is water-borne when she is just off the ground.

WATER-BRIDGE. In steam-boilers, a hollow bridge-wall, of metal, filled with water having circulation with the water contained in the boiler.

WATER-BUTT. A large water-cask. See WATER-CASKS.

WATER-CAP. A cap in a navy time-fuze, to prevent the water from entering and extinguishing the fuze.

WATER-CASKS. Casks for storing or bringing water to a ship. The following sizes of casks, with their weights when full, embrace those most in use:

Butt—110 gallons, weight 1100 pounds.

Puncheon—72 gallons, weight 720 pounds.

Barrel—36 gallons, weight 360 pounds.

Cask or kilderkin—18 gallons, weight 180 pounds.

Small casks for use in boats, about decks, etc., are called *breakers.*

WATER-CONDENSER, or WATER-DISTILLER. See DISTILLING APPARATUS.

WATER-CRAFT. All vessels plying on the water.

WATER-CROW. The shag, or lesser cormorant.

WATER-DOG. A sea-dog; an old sailor.

WATER-FLEAS. The *Entomostraca*, a group of crustacea of the genera *Cyclops* and *Daphnia.*

WATER-FOX. The carp; so called on account of its cunning.

WATER-GALL. A name for the *wind-gall.*

WATER-GAUGE. A sea-wall. An instrument to measure the rise of water. A gauge which indicates the quantity or height of level of water within a chamber or reservoir, such as a steam-boiler, etc. An instrument for indicating pressure by means of a column of water.

WATER-GAVEL (*Eng.*). Rent paid for fishing-rights in a stream.

WATER-GUARD. A custom-house officer employed to watch incoming vessels, or those passing out.

WATER-HEMLOCK. The *Œnanthe crocata*, a poisonous aquatic plant.

WATER-HORSE. Codfish stacked in a pile to drain.

WATERING-PLACE. A locality where fresh water may be procured for ships' use.

WATER-LAID ROPE. Rope laid up against the sun, or left-handed.

WATER-LEG. A space in a marine boiler between the furnaces, filled with water.

WATER-LINES. Horizontal lines supposed to be described by the surface of the water on the bottom or sides of a ship, and which are exhibited at certain parallel depths upon the sheer-plan. Of these the most important are the *light water-line* and the *load water-line.* The light water-line is the line of immersion of the ship when light or unladen. The load-water line is the line described around the ship's body when the cargo is all on board and the ship is ready for sea. In the half-breadth plan the water-lines are outward curves, limiting the half-breadth of the ship at the same height as the corresponding lines in the sheer and body plans.

WATER-LINE MODEL. A model made up from horizontal or water-lines and the sheer-lines.

WATER-LOGGED. The condition of a leaky ship when she is so full of water as to be heavy and unmanageable.

WATERMAN. A man who plies for hire on the water; a boatman.

WATERMAN'S-KNOT. A name for the *clove-hitch.*

WATER-MARK. A mark on a water-gauge indicating the height of water.

WATER-PADS. River-pirates; water-thieves.

WATER-PLOW. A kind of dredging-machine formerly used in rivers.

WATER-ROOM. The space in a steam-boiler that is filled with water.

WATER-SAIL. A small sail set under the lower studding-sail. A sail formerly set under a projecting spanker-boom, extending to the water's edge.

WATER-SCAPE. A passage for water

WATER-SHELL. A shell invented by Abel, filled with water, and containing gun-cotton in a cylinder in the centre.

WATER-SHOT. That condition of a ship

moored neither across tide nor up and down, but midway between the two positions.

WATER-SKY. A dark blue sky caused by reflection of deep water, seen in Arctic seas.

WATER-SNAKES. The marine snakes of the genus *Hydrophis*, with broad flat tails.

WATER-SPACE. The space occupied by the water in a marine boiler.

WATER-SPOUT. A vertical column of water moving along the surface of the sea, having also a gyratory motion. As considerable masses of water are raised, they are dangerous to small ships. They may be broken by firing into them.

WATER-STANG. A pole across a stream.

WATER-STOUP (*Eng.*). The periwinkle.

WATER-TANK. See TANK.

WATER-TIGHT. Well calked; staunch. Not admitting water.

WATER-TUBE BOILER. A steam-boiler in which the tubes are so arranged that the water is *within* the tubes around which the heat circulates.

WATER-WAR (*Eng.*). The *bore* of the Severn.

WATER-WAYS. Pieces of oak or yellow pine timber lying in the angle made by the top of the deck-beams and inside of the frame-timbers.

WATER-WITCH. The *dipper*, a sea-bird.

WATER-WRAITH. Supposed sea-spirits in the Shetland Islands.

Waterford, the capital of Waterford County, Ireland, on the right bank of the Suir, which forms its harbor, and is lined by a fine quay about 1 mile in length; 9 miles from the sea. Among the principal buildings are the chamber of commerce, custom-house, and artillery barracks. The city is the entrepôt for a large extent of country, the exports of which are bacon, live-stock, dairy and agricultural produce, salmon, and cotton goods. It has two large ship-building yards, and manufactories of glass and starch, with distilleries and breweries. Pop. 24,000.

Waters, Captain Daniel. In January, 1776, Capt. Waters was appointed to the schooner "Lee," of eight 6-pounders. While commanding her he captured or assisted in capturing several valuable transports, in one of which was Col. Campbell, with a part of the 71st British regiment; in another a quantity of merchandise which the British had plundered from the merchants of Boston when they evacuated that city. In command of the privateer "Thorn" of 16 guns, of Boston, Capt. Waters, in the year 1778, engaged the "Governor Tryon" of 16 guns, Capt. Stebbins, and the "Sir William Erskine" of 18 guns, Capt. Hamilton, each having a greater number of men than the "Thorn." The action lasted for two hours, when the "Tryon" struck, and the "Erskine" made sail to escape. The "Thorn" pursued her, and compelled her to strike. Capt. Hamilton and the other officers of the "Erskine" were removed on board the "Thorn," and the "Erskine" was ordered to follow in pursuit of the "Tryon," which vessel, however, escaped, owing to the darkness of the night. The next morning the "Erskine" was manned and ordered for Boston, leaving the "Thorn" about 60 men only. A few days after this the "Thorn" fell in with the "Sparlin" of 18 guns and 97 men, and after a close action of nearly an hour the "Sparlin" struck. The "Thorn" and her two prizes arrived safe in Boston. Capt. Waters was appointed by Congress a captain of the navy, March 15, 1777, upon the recommendation of Gen. Washington, by whom he had been employed, and who wrote of him in terms of high approbation.

Wattles. Bristles near the mouths of certain fish.

Wave. A volume of water raised by the action of the wind, tide, or current, upon the ocean. Waves may arise from no apparent cause, as when they precede or follow a storm. Waves are either *natural*—that is, proportioned in size to the strength of the producing force—or *accidental*, being increased or diminished by collision with other waves, concussion with intervening bodies, etc. *Simple waves* are those proceeding directly from the producing causes, without interruption in any direction, and unaccompanied by any other waves. *Compound waves* occur when several producing causes have resulted in waves of different heights, etc., as in a confused or chopping sea. So when certain waves occur, greater than the majority in the same locality, it is due to a greater cause, or to their coming from a shorter distance. Waves are in section cycloidal curves. They do not probably extend more than 2000 yards below the surface, and the effect of generating causes is less the farther you recede from the surface.

Dimensions and velocity of waves.—The velocity of waves is dependent on their length. If length (l) is known, the velocity is that that a body would acquire in falling through a height equal to $\frac{1}{2} r$, where r is the radius of a circle whose circumference equals l. This would give as a mathematical expression $v = \sqrt{\frac{l g}{2 \pi}}$. Where g is the force of gravity, and π the quantity 3.1415, etc., g may be taken as $16\frac{1}{12}$. This would then reduce to $v = \sqrt{l \frac{193}{75.396}}$. But as waves approach a shelving shore their lengths decrease, but they become higher, while their lower part decreases in velocity on account of friction, and thus they break into *surf* when their height equals the depth of the water. Dr. Scoresby, in 1850, measured Atlantic waves, finding some 43 feet high from trough to crest. Other waves in 100 feet of water were 4 to 5 feet in height, and 30 to 40 feet long, but did not extend to the bottom. He found the mean height of Atlantic waves to be 10 feet. Six hundred feet in breadth, from crest to crest, is usual in waves 30 feet high, and with a velocity of 32 miles per hour. Northwest gales caused waves off Cape Horn 40 feet high, but only 32 feet off Cape of Good Hope. *Tidal waves* are caused by the regular fluctuations of the tides. An earthquake is often accompanied by a wave, that of Lisbon being some 40 feet in height, and that at Arica, more than 50 feet high.

WAVE-LINE. A method of shaping the hull of a vessel, invented by Scott Russell, in which the lines of the vessel were cycloidal, or approaching that curve in character.

WAVESON. Goods found floating on the waves after shipwreck.

Way. The progress of a ship through the water. *Head-way*, motion ahead. *Stern-way*, motion astern. *Fresh-way*, increased motion from any cause. *To be under way*, to be in mo-

tion. *To have way*, to have motion through the water. *To gather way*, to acquire motion through the water. *To lose way*, to cease moving. See LEE-WAY.

GETTING UNDER WAY. The manœuvre by which a vessel is released from the restraint of anchors and cables and placed under the control of its motive-power.

The manner of performing the evolution may differ with the force and direction of wind, tide, or current, rig of vessel, motive-power, whether steam or sail, and the berth in which the vessel may be anchored.

Except when fixed moorings are employed, the anchor or anchors are hove up by means of the capstan, windlass, or deck-tackle.

When great haste is necessary the cable may be slipped by unshackling it as near the hawse-pipe as possible, and allowing that part connected with the anchor to go overboard, having first attached a buoy by which it can be easily recovered.

With a vessel under steam the evolution is the most simple, as she is to a great extent independent of both wind and tide. The anchor being aweigh, the engine is started, and the vessel is at once under the control of the machinery and helm.

When sail-power alone is used, the operation is more difficult, as the direction and force of wind and current must be regarded, and also the proximity of dangers or of other vessels. The cable is hove in to a short stay when sail is m[illegible]d, in the case of a square-rigged vessel, t[illegible] are braced in such a manner as to as-s[illegible]iving the required direction and head-[illegible]he vessel after the anchor is aweigh; [illegible] can only be determined by the action of [illegible]ind and current upon the vessel, their relat[illegible] strength, and the direction in which it is nec[illegible]sary that the vessel should move. The anchor is then hove up, the head-sails hoisted when the anchor is aweigh, the helm used as required to bring the vessel on her course, and the yards are trimmed as may be necessary.

The time at which the square-sails should be set may depend upon the direction of the wind with the desired course of the vessel; for if that course will bring the wind well aft, the anchor is first weighed, the vessel turned in the required direction by means of the head-sails and helm, and all sail made when she is upon her course.

With a fore-and-aft-rigged vessel the process is similar, but it is more simple on account of the advantages of rig.

To get under way from fixed moorings the cable which is shackled to the buoy is replaced by a slip-rope, which is let go at the proper moment and the delay of heaving up the anchor is avoided. In a crowded harbor it may be neces-[illegible]ary to heave up the anchor and warp the vessel [illegible]lear of others before proceeding to make sail, or [illegible] the vessel is anchored in the vicinity of dangers, a part of the manœuvre may consist in taking a temporary berth by using a kedge.—*E. T. Strong, Lieutenant U.S.N.*

Way-gate. The tail-race of a mill.

Ways. See SHIP, LAUNCHING OF.

Weak-fish. A fish of the genus *Otolithus* (*O. regalis*).

Weal (*Eng.*). A wicker-basket for catching eels.

Wear. A weir. To put a ship on the other tack by turning her bow away from the wind. *Wear* is more generally used than *veer* in this sense.

Weather. To sail to windward of. *To weather a ship*, to get to windward of her; to sustain the effects of the weather. *To weather a gale*, to come out of a storm safely. *To weather the cape*, figuratively, to become skilled. *To weather difficulties*, to contend with and surmount difficulties. *Weather side*, the side next to the wind.

The air or atmosphere, with respect to its state of dryness or moisture, heat or cold, clearness or cloudiness, or any other physical state; as, dry, cold, wet, hot, warm, calm, pleasant, windy, squally, fair, foul, stormy, rainy, cloudy, clear weather. *Stress of weather*, tempestuous weather, violent winds. The following notation is used by seamen to indicate states of the weather, in the log-book:

Beaufort Weather Notation.

b. Blue sky.
c. Clouds (detached).
d. Drizzling rain.
f. Foggy.
g. Gloomy.
h. Hail.
l. Lightning.
m. Misty.
o. Overcast.
p. Passing showers.
q. Squally.
r. Rainy.
s. Snow.
t. Thunder.
u. Ugly, threatening.
v. Visibility, clearness.
w. Wet dew.

A bar (—) under any letter augments its signification, and a bar and a dot ∸ indicates heavy and continuous weather of the kind denoted.

WEATHER-ANCHOR. The anchor laid out to windward, by which the ship will ride, when tides permit.

WEATHER-BITT. To take an extra turn of the cable about the bitts in bad weather. See BITTS.

WEATHER-BOARD. The side of the ship to windward. Planks placed in the ports of a ship in ordinary, inclined so that the water may run off.

WEATHER-BORNE. Oppressed by wind and sea.

WEATHER-BOUND. Detained by wind or sea.

WEATHER-BREEDERS. Wind-dogs, fog-dogs, and other indications of bad weather.

WEATHER-CLOTH. A covering for the hammocks, boats, etc., of painted canvas. A tarpaulin, placed in the weather rigging, to shield the men and officers on watch.

WEATHER-COIL (*Eng.*). The position of the ship when she has been reversed so as to head opposite to her former course, either by a shift of wind, or by the helm, or swell in calm weather. To resume the course when taken aback, by making a stern-board and backing around.

WEATHER-EYE. A figurative term, "*Keep your weather-eye open*"; be on your guard.

WEATHER-GAGE, or WEATHER-GAUGE. The position of a ship to windward of another,—a position of great advantage in the days of sailing-ships, but not so much so now.

WEATHER-GALL. See WIND-GALL.

WEATHER-GLASS. The barometer.

WEATHER-GLEAM. A clear sky near the horizon after stormy weather.

WEATHER-GO. The end of a rainbow in the morning.

WEATHER-HEAD. A secondary rainbow.

WEATHER-HELM. See HELM.

WEATHER-LURCH. A sudden and heavy roll to windward.

Weatherly. Holding a good wind, and making little leeway; working well to windward.

Weathermost. The farthest to windward.

Weather-rhymes. Seamen find it convenient to express many important facts in these rhymes, and a few of the more prominent are here given:

> "A weather-gall at morn,
> Fine weather all gone."

> "A rainbow (*or* red sky) in the morning,
> Sailors take warning;
> A rainbow (*or* red sky) at night
> Is the sailor's delight."

> "The evening gray and the morning red,
> Put on your hat or you'll wet your head."

> "When the wind shifts against the sun,
> Trust it not, for back it will run."

> "When the sun sets in a clear,
> An easterly wind you need not fear."

> "The evening red and morning gray
> Are sure signs of a fine day;
> But the evening gray and morning red
> Make the sailor shake his head."

> "With the rain before the wind,
> Your topsail halliards you must mind;
> But when the wind's before the rain,
> You may hoist your topsails up again."

Or

> "When rain comes before wind,
> Halliards, sheets, and braces mind;
> When wind comes before rain,
> Soon you may make sail again."

> "First rise after very low
> Indicates a stronger blow."

Or,

> "When rise begins after low,
> Squalls expect and clear blow."

> "Long foretold, long last,
> Short notice, soon past."

> "When the glass falls low
> Prepare for a blow;
> When it rises high
> Let all your kites fly."

> "Mackerel sky and mares' tails
> Make tall ships carry low sails."

Weather-roll. The roll of a ship to windward.

Weather-rope. An old term for *tarred rope*.

Weather-shore. A shore to windward of the ship.

Weather-side. The side toward the wind. At sea, the weather-side is the *royal* side,—that is, the weather gangway is not a loafing-place. The weather side of the quarter-deck is for the officer of the deck, captain, and executive-officer only, and the weather-side of the gun-deck is kept clear.

Weather-tide. A tide running toward the wind.

Weather-wheel. The helmsman on the weather-side of the wheel.

Weaver. A fish of the perch family; the *Trachinus vipera*.

Wedding-knot. A crossed seizing between two eyes in ropes.

Wedge. *Mast-wedges*, wedges placed about the mast in the partners, for confining it in place. *Launching-wedges*, wedges used to lift a ship in launching. *Set-wedge*, a wedge used to drive together two timbers.

Wedge-fid. A fid in two parts, wedge-shaped.

Weed. To clear rigging, etc., of rope-yarns.

Weel. A baited basket-trap for catching fish.

Weep. To ooze in small quantities, as the water from the side of a ship.

Weever. See Weaver.

Weevil. The *Curculio*, a variety of which is very destructive to bread, rice, etc.

Weft. See Waft.

Weigh. *To weigh anchor*, to lift the anchor from the bottom.

Weighage. A charge for weighing goods at a dock.

Weight-nails. Nails of great size, larger than deck-nails, with flat heads.

Weight of Metal. The weight of iron that a ship can throw at one round from all her guns. A line-of-battle ship, mounting 74 guns, would have thrown but 1570 pounds of metal 200 years ago, but the recent frigates, such as the "Alexandra," throw upwards of 4000 pounds, and the Italian "Duilio" will throw at a round 8000 pounds of metal.

Weir. An old term for sea-weed. An inclosure in which fish are caught. A dam across a river.

Well. An inclosure from the hold to the lower deck, protecting the pump from injury. An aperture in the upper-works of the stern of a steamer, for the propeller to travel in. A compartment in a fishing-vessel in whi[f a circ] circulates; in this fish are preserved alive[ould giv] synonymous with *belay*. *To well off*, to [...] leak by surrounding it with a temporary [...] well, carried above the water-line.

Well-boat. A fishing-boat provided [...] a well.

Well-cabin. A cabin in a small vessel entered from above, with no ports or ventilation from the sides.

Well Fare Ye! (*Eng.*). An expression formerly used to encourage the men at heavy heaving.

Well-found. Fully provided or equipped.

Wells, Clark H., Commodore U.S.N. Born in Reading, Pa., September 22, 1822. Appointed midshipman from Pennsylvania, September 25, 1840; attached to the line-of-battle ship "North Carolina," 1840; frigate "Brandywine" and sloop "Fairfield," Mediterranean Station, 1840–41; razee "Independence," Home Squadron, 1842–43; sloop "Levant," Pacific Station, 1844–45; Naval School, Annapolis, Md., 1846.

Graduated and became a passed midshipman, July 11, 1846; during the Mexican war, attached to the brig "Somers," blockading Vera Cruz, in 1846, and to gunboat "Petrel," 1846–47, during which time the latter vessel was one of Tattnall's flotilla in the attack upon the Castle of San Juan de Ulloa and the city of Vera Cruz; took part also in the capture of Tuspan and Tampico; to the East Indies, and around the world in sloop "Plymouth" and brig "Dolphin," 1848–51; receiving-ship "Princeton," in 1852, and Naval Observatory; store-ship "Fredonia," at Valparaiso, Chili, in 1852–55.

Promoted to master in 1855.

Commissioned as lieutenant, September, 1855;

Naval Observatory, Washington, D. C., in 1856; served as executive-officer of the bark "Resolute," originally an English man-of-war, abandoned in the Arctic seas, and subsequently recovered by the American whale-ship "George Henry," which vessel found her in a field of ice some 900 miles from where her crew left her. Congress, by a joint resolution dated August 28, 1856, purchased her from the salvors, and ordered her restoration to the British government, which order was complied with on her arrival in England, where she was honored by a visit from the queen of England and Prince Albert, to whom the vessel was presented by Capt. Hartstene; in the "Niagara," 1857; employed in the first Atlantic Cable Expedition, and then joined the "Susquehanna," in 1858, one of the Mediterranean Squadron; shortly afterwards the vessel was sent to the West Indies, and to Greytown, Central America, when the yellow fever broke out on board, carrying off 60 of her crew and 2 officers, which necessitated her return North, and being put out of commission; in the same year was attached to the "Water-Witch," Home Squadron; executive-officer of "Metacomet," Paraguay Expedition, in 1859; when the Rebellion broke out, was ordered as executive-officer of the "Susquehanna," then commanded by Capt. James Lardner, now rear-admiral, and which vessel took a very prominent part in the battle of Port Royal, S. C., sustaining considerable damage by the fire from the two forts, Hilton Head and Bay Point, having been struck some 35 times, and losing several of her crew, besides the wounded; received a commendatory letter from Rear-Admiral Lardner for services rendered on that occasion; the "Susquehanna" was especially mentioned in the official report of the late Rear-Admiral Dupont, who commanded the expedition; was sent several times with a detachment of sailors and marines to reinforce the "Unadilla," when much exposed to night attacks in Wright River, S. C.; was present at the occupation of Fernandina, Fla., the enemy having abandoned the place on the appearance of the expedition under the late Rear-Admiral Dupont; was then transferred to the sloop-of-war "Vandalia," engaged in the blockading of Warsaw Sound and Charleston, S. C., for a number of months; transferred to the command of the sloop-of-war "Dale," and brought her to Philadelphia.

Commissioned as lieutenant-commander, July 16, 1862; executive-officer of the navy-yard, Philadelphia, in 1863; applied for and received orders to command the "Galena," when rebuilt as a wooden vessel; joined the West Gulf Squadron in 1864; was sent several times by the late Admiral Farragut, then in command of the fleet, to shell a blockade-runner, ashore under the guns of Fort Morgan; was engaged in the battle of Mobile, and during the passage of the forts the "Galena" was secured to the "Oneida," bringing up the rear, both vessels being exposed to the fire of the forts from the commencement to the close of the action, also from the rebel ram "Tennessee"; when near the forts, a shell from the latter exploded one of the boilers of the "Oneida," which necessitated her being turned in by her consort, the "Galena," and after Capt. Mullany, of the former vessel, had his arm shot off, which occurred opposite the forts. The services of the "Galena" were duly acknowledged in the official report of the action by Admiral Farragut, and a commendatory letter was received from him, in which he says, "That in your case I depart from my usual custom, not to give letters for good conduct in time of war, where there is an immediate commander *first* to forward it, but, inasmuch as Capt. Mullany was wounded, and the command of the two vessels ('Oneida' and 'Galena') devolved upon you, and were carried through the battle with great gallantry, I take pleasure in giving my official testimony to your very meritorious conduct in that engagement, and trust that in the future it may be of service to you." East Gulf Squadron, in 1864; refitted in Philadelphia, and joined the fleet of Admiral Porter, in the James River, and remained there until the close of the war; commanded the "Kansas," South Atlantic Station, in 1864–66; visited most of the ports of that station; received a letter of thanks from the English government and the British admiral for going to the assistance of H. B. M. gunboat "Gleaner," reported to be dangerously ashore in Maldonado Bay; the services of the "Kansas" were also acknowledged by the British admiral for assisting in rescuing an English merchant-vessel, aground on the English Bank, River La Plata.

Commissioned as commander, July 25, 1866, and was one of the number selected for promotion by a board of officers for services in the war; attached to the navy-yard, Portsmouth, N. H., in 1868–70; sent to Europe, in 1870, in command of the "Shenandoah."

Promoted to captain, June 19, 1871; visited most of the ports on the Mediterranean, and during this cruise, which continued until 1874, received a letter of thanks from the Italian government, for assistance rendered to the Italian ironclad "Compt de Verde," in the harbor of Spezia, which vessel broke from her moorings in a gale of wind, and came near drifting on the rocks; received the decoration of the Legion of Honor from President Thiers, of France, and Congress, by a joint resolution, March 3, 1875, authorized its acceptance; detached from the "Shenandoah" at Key West, Fla., January 31, 1874; February 26, 1874, ordered as executive-officer of the navy-yard, Boston, Mass.; transferred as captain of the navy-yard, Philadelphia, and equipment-officer, October, 1874; thence to League Island Navy-Yard, January 1, 1876, and ordered in command of that station, January 10, 1876; detached, November 1, 1877, on the completion of the full term of three years on duty at the Philadelphia Station; 1878–79, on court-martial and board duties, and member of Board of Visitors to the Naval Academy in 1878; chief signal officer, 1879–80.

Promoted to commodore, January 22, 1880.

Welshman's Breeches. See DUTCHMAN'S BREECHES.

Welt. A batten riveted over a seam in steam-boilers. *Welt-joint*, one made with a *welt*.

Wentle-trap. A shell; the *Scalaria pretiosa*.

Werden, Reed, Rear-Admiral U.S.N. Born in Pennsylvania, 1818. Appointed from Ohio, January 9, 1834; attached to schooner "Enterprise," Brazil Squadron, 1834–35; sloop-of-war "Ontario," Brazil Squadron, 1836; sloop-of-war "Erie," Brazil Squadron, 1837; sloop-of-war

"Cyane," Mediterranean Squadron, 1838–39; Naval School, Philadelphia, 1840.

Promoted to passed midshipman, July 16, 1840; sailed for China in the sloop-of-war "Boston," October, 1840; frigate "Constellation," East India Squadron, 1841–42; sloop-of-war "Boston," East India Squadron, as master, 1842–43; receiving-ship, New York, 1844.

Commissioned as lieutenant, February 27, 1847; sloop-of-war "Germantown," Home Squadron, 1847; commanded a party of seamen at the capture of Tuspan, Mexico; receiving-ship "Vermont," Boston, 1848; sloop-of-war "Vandalia," Pacific Squadron, 1849–52; naval rendezvous, Baltimore, 1853; sloop-of-war "Albany," Home and West India Squadrons, 1853–54; special duty, West Indies, 1855; Naval Observatory, Washington, D. C., 1856; frigate "Cumberland," on the coast of Africa, 1857–59; frigate "Minnesota," Home Squadron, 1861; commanding steamer "Yankee," North Atlantic Blockading Squadron, 1861; commanding steamer "Stars and Stripes," North Atlantic Blockading Squadron, 1862; at the capture of Roanoke Island and Newbern; commanding steamer "Connemaugh," South Atlantic Blockading Squadron, 1862–63.

Commissioned as commander July 16, 1862; navy-yard, Philadelphia, 1864; fleet-captain, East Gulf Blockading Squadron, 1864–65; commanding "Powhatan," East Gulf Blockading Squadron, 1865; blockaded the rebel ram "Stonewall," in the port of Havana, West Indies, until her surrender to the Spanish government; special duty at navy-yard, New York, 1865; commanding "Bienville," West Indies, 1866.

Commissioned as captain, July 25, 1866; navy-yard, Mare Island, California, 1868–71.

Commissioned as commodore, April 27, 1871; commanding naval station, New London, 1872–74.

Commissioned as rear-admiral, February, 1875; commanding South Pacific Station, 1875–76. Retired March 27, 1877.

West. The point ninety degrees to the left of north. So called in all European languages, except Italian, where it is *Ponente* (*setting*).

Westerly. Moving toward the west, as a current, or from the west, as a wind. Tending toward the west.

Westing. The distance in nautical miles made good to the westward.

West-country Parson (*Eng.*). A fish; the hake (*Gadus marducius*),—so called from a black streak on its back.

Wester, or Waster (*Eng.*). A salmon trident.

Wet. *To wet sails*, to throw water on the sails, in order to make them hold wind better. This was formerly done with a *skeet*, but afterwards a pump and hose were substituted. *To wet a commission*, to give an entertainment on getting a new commission. *Wet provisions*, salt beef and pork, vinegar, molasses, canned beef, and spirits. *Wet goods* are charged to the owner and master of a vessel.

Wethers. The flukes of a harpoon.

Wet-nurse. This term is used to signify an officer acting as an instructor over a junior in watch-duty. See Nurse.

Wexford, capital of Wexford County, Ireland, on the right banks of the Glaney, where it widens into Wexford harbor. The city contains a chamber of commerce, ship-building docks, some malting establishments, and has an active export trade in cattle, dairy and agricultural produce, timber, tallow, hides, cotton, yarn, and wool. Pop. 13,000.

Whale. The popular name of the larger cetaceans, particularly of those belonging to the families Balænidæ and Physeteridæ, or Catodontidæ. The latter of these families has been already noticed under Cachalot (which see). The baleen whale, popularly known as the Greenland Whale (*Balæna mysticetus*), derives its name from the plates of whalebone, or baleen, with which its mouth is furnished in lieu of teeth. These are arranged in two series, consisting each of several hundred plates, which are suspended from the roof of the mouth, extending from each side of its middle line like the barbs of a feather, and terminating in a fringe of fibres or pliant bristles. Through this apparatus are strained out of the water containing them the small crustaceans and mollusks which constitute the food of the whale, the water being allowed to escape by the sides of the mouth. Only very small animals can pass through the gullet of the whale on account of its extreme narrowness, its diameter, even in a large whale, being, it is said, not more than an inch and a half. The head is very large, constituting from a third to a fourth of the whole length of the animal, which varies from 50 to 70 feet. The skull is unsymmetrical, the right side being larger than the left. The eyes are small, but the animal's sense of sight seems to be acute. The mouth is very large. The tongue is a soft, thick mass, not extending beyond the back of the mouth. The flesh is red, firm, and coarse. The skin is naked, with the exception of a few bristles about the jaws, and its surface is moistened by an oily fluid. The lower surface of the true skin extends into a thick layer of blubber,—an open net-work of fibres in which fat is held, and which serves the double purpose of keeping the animal warm and of making the specific gravity of the body much lighter than it would otherwise be. In the genus *Balæna* there is no dorsal fin, nor elevation of the back corresponding to it, as in some of the family. The pectoral fins are 8 or 9 feet long, 4 or 5 broad, and are placed about 2 feet behind the angles of the mouth. The tail-fin consists of 2 lobes of great breadth, measuring from 20 to 25 feet across in the larger specimens, and is wielded by muscles of enormous power. It is this part which constitutes the animal's sole organ of offense and defense. The body is thickest just behind the pectoral fins, whence it tapers conically toward the tail, and slightly toward the head. On the highest part of the head are situated the blow-holes, which are from 8 to 12 inches long, but of comparatively small breadth. The upper parts of the body are velvety black,—but in very old whales sometimes become piebald,—the lower parts are white. The whale has usually but one young at a birth. The period of gestation is unknown, but that of suckling lasts a year. The mother manifests great affection for her offspring.

The Southern, or Cape Whale (*Balæna Australis*), formerly regarded as identical with the Greenland Whale, is now considered as a distinct species, the head being smaller in proportion than that of the northern species, and the color

a uniform black. It attains a length of 50 or 60 feet, and is usually found in comparatively shallow water near the coasts. Its range embraces not only the colder parts of the southern hemisphere, but also the temperate regions and the tropics. Another variety, the Right Whale (*Balæna cisarctica*), heretofore identified with the Greenland Whale, is now recognized as more nearly resembling the Cape Whale. It differs from the former in having the body more slender, and the head proportionally smaller; the under jaw very deep, round, and broad; and the plates of baleen comparatively short. It is of a black color, except as to the lower part of the head, which is a brilliant white.

The species of the genus *Megoptera* are called Hump-backed Whales. They have a rudimentary dorsal fin, in the form of an elevation of the back. There are several species, but some of them are very imperfectly known.

The genus *Balænoptera*, *Physalus*, or *Rorqualus*, belonging to the same family (*Balænidæ*) to which the Greenland Whale belongs, is distinguished by its species having a dorsal fin; an upper jaw less arched than in the Greenland Whale; much shorter plates of baleen, or whalebone; and along the throat and belly numerous longitudinal folds, allowing the distention of the integuments so as to form a great pouch for the reception of water and prey, to be afterwards sifted by the plates of baleen. The cetaceans of this genus are the largest animals now existing, their length being greater, and their girth at least as great as those of the Greenland Whales.

WHALE-BIRD. A small bird seen in whaling-grounds, hovering about shoals of whales, hunting for food.

WHALE-BOAT. A long, narrow boat, from 20 to 50 feet in length, and from 4 to 10 feet beam, sharp at both ends, and admirably fitted for all uses at sea. Whale-boats are supplied to men-of-war, from one to three to each, and are either *single-banked* or *double-banked*. Some gigs are whale-boats. These boats are best in a surf, and they should then be steered with a long oar instead of a rudder. See SURF.

WHALE-CALF. The young whale.

WHALE-CHARTS. Charts prepared by Commodore Maury, giving the localities where whales abounded.

WHALE-FISHERIES. The Northmen were the first to hunt the whale before the 10th century. After them the Biscayans engaged in the whale-fishery from the 12th to the 15th centuries. But the Dutch and English were the first to hunt in Arctic regions, beginning in 1600. Large bounties were paid to whale-ships, and companies formed to prosecute the fisheries. The Dutch fisheries flourished some 30 years, the English much longer. In 1789 the English had 161 vessels engaged in the whale-fisheries, but this number diminished steadily to 82 in 1795, to 61 in 1800, then increased gradually to 91 in 1805, and 112 in 1814, and in 1815 there were 150 vessels and 6000 men engaged in it. From this time it has gradually declined. Hull, Peterhead, and London are the principal whaling ports. The United States began the hunt for whales in 1690, and from 1758 to 1775 Massachusetts alone sent out annually 183 vessels north and 121 south to fish for whales. In 1858, 680 ships were employed, but since then the trade has very much declined. Nantucket, New Bedford, and Gloucester have been the great whaling ports. The word *whale-fisheries* also is used to denote the localities in which the capture of whales is carried on. See WHALING-GROUND.

WHALE-LINE. Rope about 2 inches in circumference, made of the best Russia hemp, tarred and laid up by hand. It is used for harpoon-lines. Is also made of manilla hemp.

WHALER. A whaling-vessel, or one employed in the whale-fishery. A man employed in the whale-fishery.

WHALE'S FOOD. The *Clio borealis*, a mollusk on which the whale feeds.

WHALE-SHOT. Sperm oil when just from the whale.

WHALING-FLEET. The body of whaling-vessels belonging to a port or country.

WHALING-GROUND. The localities in which whales are found. For the right whale this is on the coasts of Greenland and in Davis Strait, and in the North Pacific and Arctic Oceans; for the southern whale, in the South Pacific and Antarctic Oceans; for humpbacks, the neighborhood of the Bermudas; for sperm-whales, in all tropical and temperate seas.

WHALING VOYAGE. A voyage out after whales, and back with the oil.

Whanger. A fish-curer in Newfoundland.

Whapper. A large turtle, of 7 to 8 hundred-weight, found near Ascension Island.

Wharf. A structure of wood, iron, or stone erected on the shore at the water's edge, for the convenience of vessels in loading and unloading. *Gun-wharf*, a wharf at an ordnance-yard or in a navy-yard, appropriated to the use of the ordnance department. *Sufferance-wharf*, in English law, is a wharf where only certain goods may be landed. Wharves where all kinds of goods are landed are there known as *legal quays*. *Sheer-wharf*, a wharf in a navy-yard on which the sheers are erected.

WHARFAGE. Wharves in general. *Wharfage-dues*, dues or fees for landing or shipping goods at a wharf.

WHARF-BOAT. A boat moored at the side of a river and used as a wharf.

WHARF-HOUSE. A house built on a wharf.

WHARFINGER. One who keeps a wharf, or who has the care of it.

WHARF-RATS. The small boys and loafers that infest wharves in large cities.

WHARF-STEAD (*Eng.*). A river-ford.

What Ship is That? A quizzing question put to a sailor using a long word.

Whaup. The large curlew, *Numenius arcuatus*.

Wheel. A circular frame connected to the tiller by the wheel-ropes. In small craft it is not necessary.

WHEEL-HOUSE. A small house erected on the deck, hurricane-deck, or bridge of many ships for the purpose of sheltering the helmsman. The *paddle-box* of a steamer.

WHEEL-ROPES. Ropes or chains leading from the tiller or helm through blocks in the decks and trunks under the beams to the barrel of the steering-wheel, where they are fastened. Soft, pliable rope must be used. In the U. S. navy *hide-rope* is generally used, and wire-rope for steam steering-gear. See STEERING APPARATUS, RUDDER.

Wheft. See WAFT.

Whelk. A shell-fish; the *Buccinum undatum*.

Whelps. The projecting parts on every other square of a capstan-barrel.

Where Away? A query in regard to the bearing of an object reported by the look-out.

Wherry. A decked vessel used in fishing in English waters, sometimes having two lug-sails, at others two shoulder-of-mutton sails. A small light row-boat for one person.

Whiff. A sudden and transient puff of wind. A fish of the genus *Pleuronectus;* the *Rhombus cardina.* A fish of the turbot group; the *Rhombus megastoma.* To fish for mackerel by trolling from a boat in rapid motion.

Whimbrel. The smaller curlew, *Numenius phœpus.*

Whimsey. A small crane for hoisting goods into warehouses.

Whinyard (*Eng.*). An old name for a hanger or cutlass.

Whip. A small and light purchase. *Single whip*, a rope rove through a single block. *Double whip*, a rope rove through two single blocks, the standing-part being near or fast to the upper block. *Whip upon whip*, one whip applied to the falls of another. *Whip and runner*, a whip whose block is attached to a pendant, itself rove through a block and applied to the weight. *To whip*, to bind the end of a rope with twine to prevent it from unlaying.

WHIPPING. Turns of small-stuff or twine around the end of a rope to keep it from unlaying.

Whip-jack. A fresh-water sailor.

Whippers (*Eng.*). Men who clear colliers in the Thames River.

Whip-ray. The *sting-ray*, or *stingaree.*

Whip-staff. A strong bar fastened to the tiller, to move it more easily.

Whirler, or Troughton's Top (*Eng.*). An instrument intended to serve as an artificial horizon at sea, counteracting the motion of the ship by a centrifugal motion given to it.

Whirlpool. An eddy or vortex, where the water moves in circles, caused by the meeting of powerful currents. The most celebrated ones are the *Garofalo*, or ancient Charybdis, on the coast of Sicily, and the Malström and Saltenström, on the Norway coast.

Whirls. Small hooks set in wooden or iron cylinders, which are moved by a band extending to the wheel, and generally used in sets of three. They are used to give the twist to the yarns in making rope. See ROPE, SMALL-STUFF.

Whirlwind. A violent wind moving on its axis, and having also a progressive movement.

Whiskers. Two booms, or iron bars, projecting on either side of the bowsprit, serving as outriggers to the jib-guys. They are the successors of the spritsail-yard. Sometimes they are dispensed with in small vessels, and instead of them a small boom (called a *spread-yard*) is lashed across the forecastle.

Whistle. Whistling is not tolerated in a man-of-war. It is an old superstition that whistling in a calm brings on a breeze, and also that whistling during a gale increases its violence. *To whistle psalms to the taffrail*, to give unheeded advice. *To wet one's whistle*, to take a drink.

Whistle-fish. A species of cod; the *Motella vulgaris.*

White-bait. A small sea-fish of the herring kind; the *Clupea alba.*

White Boot-top. A painted line or ribband carried around the ship under the hammock-nettings.

White-caps, or White-horses. The white patches caused by the breaking of the crests of waves in deep water. They are caused by the wind, and indicate that it will freshen.

White-coat. The skin of a young seal.

White-feather. A symbol of cowardice,—a white feather in a cock's tail being considered a proof of cross-breeding.

White-fish. The *hard-head.* A small fish (the *Alosa menhaden*), used for fertilizing land. A fish of the salmon family (*Coregonus albus*), abundant in the American lakes. The *Beluga catodon*, or white-whale. A general name for ling, cod, halibut, haddock, and tusk, and for roach and dace, whose scales are used to make artificial pearls.

White-herring. A pickled herring. A fresh or unsalted herring.

White-horse, or White Horse-fish. A ray; the *Raia fullonica.* See WHITE-CAPS.

White-lappel (*Eng.*). A nickname for a lieutenant, alluding to white lappels formerly worn on the coat.

White-nun. The *Mergus albellus*, a merganser, or goosander, with a white belly, breast, and throat.

White-powder. A chlorate explosive mixture, composed of 3 parts of potassium chlorate, 1 part white sugar, 1 part potassium ferrocyanide. It is also called German powder. It is extremely sensitive, and dangerous to use. See EXPLOSIVES.

White-rope. Untarred hemp rope.

White-shark. See SHARK.

White-squall. See SQUALL.

White-tape (*Eng.*). A smuggler's name for gin.

White-water. Water over shallow sand-banks, white by the reflection from the bottom.

White-whale. The *Beluga.* See WHALE.

Whiting, William B., Commodore U.S.N. Born in New York, November 13, 1813. Appointed from New York, February 2, 1829; attached to receiving-ship at New York, 1831; sloop "Falmouth," Pacific Squadron, 1831–33; surveys of San Lorenzo, including Boca del Diablo, 1832; surveys of Bays of Ferrol and Samana, and island of Lobos de Tierra, 1833; schooner "Dolphin," Pacific Squadron, 1833; frigate "Potomac," Pacific Squadron, 1833–34; receiving-ship at New York, 1835; frigate "Constellation," West India Squadron, 1835–36.

Promoted to passed midshipman, June 4, 1836; receiving-ship at New York, 1836–37; coast survey, 1837–42; survey of Potomac, 1842–43; frigate "Macedonian," coast of Africa, 1843–45; surveys of Las Palmas and Bay of Gando, 1844; Observatory, Washington, 1845–50; was employed, 1847, under direction of the Navy Department, in drawing plans of the castle of San Juan de Ulloa and the approaches to Vera Cruz; coast survey, 1851–52; sloop "Vandalia," East India Squadron, 1852–56; surveys of Mew Bay and Cumsingmoon, 1852; surveys of west coast of Loo Choo, including Deep Bay, 1853; surveys of Toobootch, Shah Bay, Yeddo Bay, and Hakodadi, 1854; retired, 1855; Naval Observatory, Washington, 1861–71.

Commissioned as commander, July 21, 1861.
Commissioned as captain, 1867.
Commissioned as commodore, 1871.

Whiting. A sea-fish; the *Merlangus vulgaris*. The *Salmo albus*, or white-salmon.

Widow's Men (*Eng.*). Imaginary men formerly borne on the ship's books, for pay in every ship in commission. The pay was applied to a widow's pension fund.

Wild. *Wild-roadstead*, an unsheltered, open roadstead. *To fire wild*, to fire guns with bad aim. *To steer wild*, to steer badly.

Wild-fire. See FIRE-SHIPS.

Wild-wind. An old term for a whirlwind.

Wilkes, Charles, Rear-Admiral U.S.N. Born in New York City, in 1801. He entered the navy as midshipman, January 1, 1818, joining the "Franklin," 74, Capt. Stewart, going to the Mediterranean; was transferred to the "Guerriere," but back again to the "Franklin" in 1820; went to the Pacific Station in the same ship in 1821, returning in 1822; on furlough in 1823–25.

Promoted to lieutenant, April 28, 1826; on waiting orders, 1827–28. In 1829, was on duty, preparing for exploring expeditions, and in 1830, was on duty at Chart Depot, in Washington. In 1830, was attached to the "Delaware," 74, on the Home Station, and in 1831, to the sloop "Boston," in the Mediterranean. In 1833 he was on duty again, preparing for explorations. From 1834–37, was on special duty, being in charge of chronometers part of the time in 1835. In 1838, was ordered to the brig "Porpoise," to prepare for, and in August sailed on an exploring expedition, in command of 2 sloops, a brig, store-ship, and 2 schooners. While absent, he explored the islands of the Pacific, and made important discoveries in the Antarctic continent, and returned to New York in June, 1842. Was tried on charges of irregularities, and reprimanded for illegal punishments. He was in the coast survey during 1842–43, and was promoted to commander, July 13, 1843; was on special duty at Washington, connected with the exploring expedition, from 1844–61; was promoted to captain, April 4, 1855. He wrote the narrative of the expedition, was the author of the volume on "Meteorology," and also published, in 1849, a work called "Western America," and in 1856, "Theory of the Winds." He was given command of the "San Jacinto" in 1861, and sailed in search of the privateer "Sumter," and on the 8th of November took from the English mail-steamer "Trent" the persons of Messrs. Mason and Slidell, Confederate commissioners to England. He was complimented for this by the Secretary of the Navy, although the prisoners were given up, it being an illegal capture. In 1862, commanded James River Flotilla; shelled City Point, August 28; in 1863, commanded a special West India Squadron, and captured many blockade-runners.

Promoted to commodore, July 16, 1862, and retired in 1864.

Promoted to rear-admiral, July 25, 1866, and died at Washington on the 8th of February, 1877, aged 76, having been in the service 59 years.—*F. S. Bassett, Lieutenant U.S.N.*

Williwaw. A light, sudden whirlwind.

Willock. The guillemot (*Uria troile*).

Wilson, Theodore D., Naval Constructor U.S.N. Born in Brooklyn, May 11, 1840; served a regular apprenticeship as shipwright under Naval Constructor B. F. Delano, U.S.N., at the navy-yard, Brooklyn, N. Y.; served for three months at the outbreak of the war as a non-commissioned officer in the 13th Regiment, N. Y. M. On the return of the regiment he was appointed a carpenter in the navy from August 3, 1861, serving afloat in the North Atlantic Blockading Squadron until 1863, during which time he took part in the fight with the "Merrimac," and was in several minor engagements on the coast. On December 15, 1863, he was ordered to special duty under Rear-Admiral Gregory, general superintendent of work outside of navy-yards, and by his order was intrusted with the building, repairing, and alterations of scores of vessels, involving the exercise of great judgment and skill.

Mr. Wilson remained on this important duty until May 17, 1866, when he was appointed assistant naval constructor in the navy. Ordered to duty in charge of the construction department of the navy-yard, Pensacola, Fla.; detached December 28, 1867, he was ordered to the navy-yard, Philadelphia, Pa. While attached to this station as assistant to Naval Constructor S. M. Pook (deceased) he finished and launched the "Omaha," completed the rebuilding of the "Juniata," commenced the rebuilding of the frigate "Brooklyn," and repaired the "Sangamon" and "Dictator"; detached on the 3d of July, 1869, he was ordered to the Naval Academy as instructor in ship-building and naval architecture, where he remained for a period of four years, giving great satisfaction. During the summer of 1870 he was ordered by the Secretary of the Navy to England and France on special service, for the purpose of observing personally the improvements in the construction of iron vessels of war. This duty was satisfactorily performed and much reliable information obtained. Detached from Naval Academy July 16, 1873, he was ordered in charge of the department of construction and repair at the navy-yard, Washington, D. C., and while there rebuilt the sloop-of-war "Shawmut" and fitted her for sea, and put the sloop-of-war "Nipsic" in frame.

He was promoted, and commissioned as naval constructor from July 1, 1873; detached and ordered to the navy-yard, Portsmouth, N. H., June 1, 1874, where he has been stationed for a period of seven and one-half years. He had the supervision of the work on the "Plymouth," "Kearsarge," and "Wachusett," finished the sloop-of-war "Enterprise," launched the sloop-of-war "Essex," fitted for sea the sloop-of-war "Marion," rebuilt and fitted out the sloop-of-war "Ticonderoga," rebuilt and fitted for sea the corvette "Lancaster," the latter vessel being almost entirely rebuilt from his own designs.

Mr. Wilson is a member of the Institution of Naval Architects, England, and is the author of "Ship-building, Practical and Theoretical," which is now used as the text-book at the Naval Academy. He has been longer in the service than any officer on the constructors' list, and is the only officer who has served actively both in the army and navy, ashore and afloat. Selected one of two constructors from the active list as a member of the Naval Advisory Board, for the

purpose of recommending a plan for the reconstructing of vessels in the navy.

Winch. A simple machine having a horizontal shaft turned by a crank or lever. *Steam-winches* are frequently furnished to ships for hoisting boats, ashes, etc. A *rope-winch* is used in laying up rope. See Rope.

Wind. To turn a ship end for end by warps, boats, a tug, or by her sails or engine. To blow a call; to pipe. *To wind away*, to steer through a tortuous channel.

Wind. A current of air in motion. The winds were the mariner's chief reliance until the advent of steam. On them all sailing-ships depend, and they have always been the study of sailors. The Greeks personified the winds. Boreas, Zephyrs, Euros, and Notos (north, south, east, and west winds) were to them actual persons, causing disasters or bringing favoring breezes. A general belief existed in the Middle Ages that they were salable. The Finns and Huns sold them for centuries, and Eric the Norseman was quite an agent of the elements. They delivered 1, 2, or 3 knots in return for fees; to untie 1 brought a good wind, 2 a very strong wind, and 3 a tempest. Bessie Miller, an Orkney maiden, sold them as late as 1814 to the fishermen, at 6[d] a man. Witches were generally believed to deal in them, and the spirit of the storm-wind has yet his believers.

Winds are named from the direction from which they blow, and receive the compass-names, as *west winds*, *east winds*, etc. *Reigning winds*, *leading winds*, *trade-winds*, *monsoons*, *cyclones*, *typhoons*, *sea-* and *land-breezes*, also are designations of particular classes of winds A gentle wind is a *zephyr*, while a *breeze* is more forcible, a *wind* next, a *gale* next, then a *tempest*, and a *hurricane* or *tornado*. In the Mediterranean various local names apply to the winds, as *Tramontana* and *Gli Secchi* (the dry winds) for the north winds, *Solano*, *Levante*, *Bentu de Sole*, and *Chocolatero* for the east winds, *Mezzo giorno*, *Simoom*, and *Siume* for southerly winds, *Ponente* and *Liberator* for west winds, *Gregale* and *Bora* for northeast winds, *Scirocco*, *Maledetto* (evil), *Levante*, *Molezzo*, and *Furiante* (when strong) for the southeast winds, *Vendavales*, *Lebeches*, *Virazones*, *Labeschades* (when squally), *Ouragani* (when tempestuous), *Labbetch*, and *Siffanto* for southwest winds, *Mistral*, *Mistrasu*, *Bize*, *Grippe*, *Vent de cers*, *Maestrale*, and *Mamatete* (when light) for the northwest winds, *Provenzale* for north-northwest winds, *Imbattu*, for sea-breezes, *Rampinu* for land-breezes, *Raggiature* for land-squalls, *Burrasche* and *Raffiche* for hard squalls, *Bonaccia* for calms, and *Golfada* for hard gales.

Generally speaking, winds are *prevailing winds*, *periodical winds*, or *variable winds*. Prevailing winds are those that blow a great part of the time from one direction. Such are the *trade-winds*, and others less known. South and southwest winds prevail on the west coast of Africa all the year. Periodical winds are those that blow a certain part of the time in each year from a certain direction. Such are the *monsoons*. Besides these, on the coast of Africa from Cape Verde to Sierra Leone southwest winds blow from June to September, and northeast winds from October to May, and on the east coast of Africa northerly and southerly winds alternate in winter and summer. The *Levante* blows from the northeast in the Ægean Sea from 9.30 A.M. during the day only. As a rule, beyond the trade-winds the winds prevail toward the pole. But by far the greater part of the inter-trade region is occupied by variable winds, depending on circumstances of temperature, pressure, moisture, and magnetism for their force and direction.

As a general rule, barometric changes of pressure are followed by changes in the wind, and these, in connection with careful observations of changes in temperature and the hygrometric condition of the atmosphere, indicate to the mariner to some extent the nature of the change in the wind. When the wind in the northern hemisphere shifts with the sun—*i.e.*, from left to right—it is said to *haul*, when in the opposite direction it is said to *back*. The former change is more of a permanent character, the latter a temporary and unsettled change. In the southern hemisphere, this is reversed. In general, a rise in the barometer indicates polar, and therefore drier, winds; a fall, equatorial and wet winds. A violent wind is a *gale*, *storm*, *hurricane*, *typhoon*, *cyclone*, or *tornado*. The following table gives the rate and pressure of winds, with the adopted notation in use among sailors, devised by Beaufort:

Miles per Hour.	Feet per Minute.	Pressure in Pounds per Square Foot.	Beaufort Number.	Description of Wind.	Speed of a good ship, or sail she could carry.
0	00	.000	0	Calm.	*Nothing*—all sail.
1	88	.005	1	Light air.	All sail—just steerage-way.
2	176	.020	2	Light breeze.	One to two knots.
3	264	.044			
4	352	.079	3	Gentle breeze.	Three to four knots.
5	440	.123			
10	880	.492	4	Moderate breeze.	Five to six knots.
15	1320	1.107			
20	1760	1.970	5	Fresh breeze.	Close-hauled royals.
25	2200	3.067	6	Strong breeze.	Single reefs, topgallant-sails.
30	2640	4.429			
35	3080	6.027	7	Moderate gale.	Double reefs and jib, etc.
40	3520	7.870			
45	3960	9.900	8	Fresh gale.	Three reefs and courses.
50	4400	12.304	9	Strong gale.	Close reefs and courses.
60	5280	17.733	10	Whole gale.	Main-topsail and foresail, close-reefed.
70	6160	24.153	11	Storm.	Storm stay-sails.
80	7040	31.490	12	Hurricane or tornado.	No canvas.
100	8800	49.200			

With regard to the position of the ship with reference to the wind, she is *close to the wind*, *by the wind*, or *on a wind*, when the yards are braced up and the wind blows from a quarter from 4 to 6 points from the bow. The wind is a *head wind*, a *leading wind*, a *fair wind*, a *free wind*, a *large wind*, or a *scant wind*, as it blows toward the sails from different angles with the keel. *In the wind*, with the wind ahead, so that the sails shake. *In the wind's eye*, directly toward the wind. *Down the wind*, in the same direction the wind is blowing. *Between wind and water*, near the water-line; in that sector of the ship's side which, when she rolls, is covered and uncovered by the water. *All in the wind forward, sir!* a notification from the officer of the forecastle that the head-sails shake. When the wind goes toward the bow of a ship it is said to *haul*, when towards the stern, to *veer* or *draw aft*. *Wind in the teeth*, wind directly ahead, or against the course.

WIND-BANDS. Long stratus clouds, supposed to indicate wind.

WIND-BOUND. Detained by contrary winds.

WIND-FALL. A violent rush of wind from high land. Also, a good stroke of luck.

WIND-GAGE. See ANEMOMETER.

WIND-GALL. A luminous halo on the edge of a distant cloud, where there is rain, generally to windward, and the precursor of bad weather. Similar halos are seen to leeward.

WIND-RODE. A ship is *wind-rode* when riding by the force of the wind, independent of the tides, or against their force.

WIND-SAIL. A funnel of canvas, used to admit air into the lower part of a ship. It is circular, distended by hoops, and hoisted by halliards, while near the head large flaps, extended by bowlines, catch the air and direct it into an aperture in the side of the wind-sail. Another kind has the head entirely open, and there are four flaps, so as to fix it, and avoid constant trimming with every shift of wind or swing of the ship. A wind-sail is also sometimes used protruding from the hawse-holes, to catch the wind when at anchor. Wind-sails are named from the hatches down which they lead, or from the part of the ship they ventilate.

WIND-TAUT. A vessel at anchor heeling over to the force of the wind.

WIND-TIGHT. A cask when it does not leak is wind-tight and water-tight.

WINDWARD. Toward the wind. The weather-side. *To lay an anchor out to windward*, a figurative expression, signifying to adopt precautionary measures; borrowed from a seamanlike manœuvre in times of necessity. *To ply to windward*, to work the ship on a wind.

WINDWARD-SAILING. Turning to windward, or navigating a ship toward the wind by making frequent tacks.

WINDWARD-SET. A set toward the wind, or a flow in that direction.

WINDWARD-TIDE. See WEATHER-TIDE.

Windage. The crescent-shaped space between a shot and the bore of a gun, due to their difference of diameter.

Winding-tackle. See TACKLES.

Windlass. A machine moved by levers or bars, used in small vessels for raising the anchor. A large horizontal cylinder of wood rests in upright pieces bolted to the deck, and called *carrick-heads*, *carrick-bitts*, *windlass-heads*, or *windlass-bitts*. Strong knees support these bitts. On the horizontal roller or *barrel* are *whelps*, and around it the chain is wound when heaving up. Two *chocks* support the middle portion, and on it two *ratchet-pawls* work in ratchets on the cylinder. The ordinary windlass is moved by hand-spikes inserted in holes in the cylinder. Another has brakes like a pump, whose rods are connected to pawl-boxes on either side of the cylinder. These have pawls which take in ratchets on the cylinder on the up and down stroke. Another form has a brake acting by friction on the cylinder on the up-stroke.

The windlass is more powerful than the capstan, but fewer men can be used with it. In the lever-windlass, when the levers are perpendicular, each man exerts from 20 to 30 pounds on it, but when they are horizontal, this is increased to 140 or 150 pounds. A *windlass-capstan* is a combination of the two, in which a windlass moves the spindle of a capstan by gearing. It was patented in 1866, but is little used.

WINDLASS, SPANISH. See SPANISH WINDLASS.

Windle-stray. A kind of sea-side grass or reed.

Windlipper. The first ripples on smooth water, caused by a breeze.

Wine and Beer. These are allowed to seamen in all navies except that of the United States. (See SPIRIT-RATION.) Officers are allowed fermented drinks, but not spirituous liquors.

Wine of Height (*Eng.*). An extra allowance formerly given to men on the accomplishment of some difficult navigation.

Wing. The projecting part of a steamer's deck before and abaft the paddle-boxes. The extremities of a fleet or squadron, either in line or in any order of sailing. The part of the hold and orlop nearest the side of the ship. The wings near the water-line should be kept clear, so that access may be had to them during action to stop shot-holes. *To wing up ballast*, to carry the bottom weights high up to ease the rolling motion.

WING-AND-WING. Before the wind with studding-sails on both sides. In a fore-and-aft-rigged vessel, before the wind with the mainsail on one side and the foresail on the other.

WING-PASSAGE. A passage formerly left in large ships about the wings, to afford a ready access to the side of the ship in action.

WING-SAIL. A quadrilateral sail bent to hoops on the mainmast, and to the gaff of a ketch.

WING-TRANSOM. The largest or main transom in the stern-frame.

WING-WALE. The sponson-rim.

Winnold-weather (*Eng.*). Stormy March weather.

Winter-fish (*Eng.*). Dried cod and ling.

Winter-gull, or Winter-mew. A gull; the *Larus canus*.

Winter-quarters. The quarters of a blockading fleet during the wintry gales. In the Arctic, the spots where ships winter from October to July.

Wiper. See CAM.

WIPER-SHAFT. A shaft carrying a wiper.

Wire. Plain, galvanized, tempered, annealed, and galvanized annealed iron and steel wires

are used in making wire-rope, each possessing peculiar properties.

Wisby, Laws or Code of. An early maritime code framed at Wisby, in England. See MARITIME LAW.

Wise, Henry Augustus, Captain U.S.N. Born in Brooklyn, N. Y., May 2, 1819; died at Naples, April, 1869. Son of George Stuart Wise, an officer of the U. S. navy, who came from an old royalist family, several of whom were taken prisoners, after the Penruddock rebellion, and sent to Virginia, about 1665. At the age of 14, by the influence of his cousin, Gov. Wise, he was appointed a midshipman, and first sailed under Capt. John Percival, the "Jack Percy" of his "Tales for the Marines." He served in the squadron on the coasts of Florida during the Seminole war, and after promotion to a lieutenancy, in the Pacific, in California, and Mexico during the war of 1846–48. On his return to the United States he married the daughter of Edward Everett. In 1862 he was promoted to commander, and made assistant chief of the Bureau of Ordnance and Hydrography; captain, January, 1867; resigned his connection with the Ordnance Bureau, January, 1869. He published in 1849, "Los Gringos"; in 1855, "Tales for the Marines"; "Scampavias," 1857; "Captain Brand of the Schooner Centipede," 1860.

Wishes. Lowlands frequently overflowed.

Wishy-washy. Weak; over-watered.

Wismar. A fortified seaport town of North Germany, at the head of a deep bay of the Baltic. It has manufactories of tobacco and sail-cloth, and important breweries and distilleries. Its harbor is commodious, and nearly landlocked by the island of Poel. It has large ship-building docks. Pop. 15,000.

With, Withe, or Wythe. An iron hoop or ring fitted to the end of a spar or boom, to pass another spar through, so as to hold it in place.

With the Sun. In the direction in which the sun appears to move,—*i.e.*, from left to right. In the direction in which the hands of a watch move.

Withershins. See WIDDERSHINS.

Witheys (*Eng.*). A low place near rivers where willows grow.

Witness. A pile of earth left in digging a dock, etc., to judge how much has been removed.

Witness. Military and naval courts summon witnesses through the judge-advocate or recorder. Any person subject to the jurisdiction of the United States can be compelled to appear and testify. In the event of refusal, the judge-advocate is authorized to issue a process of attachment, similar in form to that employed by the civil courts, and the person appointed to serve such attachment is justified in using needful force to secure obedience. The same rules of evidence obtain in the main as in civil courts, and a witness cannot be required to criminate himself. All testimony is given under oath or affirmation (see OATHS), and a witness who willfully gives false evidence, or corruptly suborns others to do so, "shall, and may be prosecuted in any court of justice in the United States." A witness who refuses to testify, or "behaves with contempt to the court, may be imprisoned, at the discretion of the court, for a term not exceeding two months."

Witnesses are not to be summoned at the expense of the United States, unless their testimony is material and necessary. Civilian witnesses, not in government employ, are entitled to mileage at the rate of 8 cents per mile, and to a per diem of 2 dollars, from and to their domiciles. They must have certificates of attendance from the judge-advocate. Those belonging to the navy and marine corps receive mileage both ways if officers, and actual transportation if enlisted men (Navy Regulations, 1876). Witnesses necessary to substantiate charges against merchant-seamen, sent home on men-of-war from foreign stations to be tried, must accompany them (*ibid.*). Naval witnesses are to appear in service dress (*ibid.*). All witnesses are required to withdraw when charges and specifications are read, and to remain outside of court until called. Exceptions to competency are to be made before the witness is sworn, but, if at any stage of a trial incompetency appear, the court may stop the witness and disregard the testimony. Witnesses must be sworn in open court, and in the presence of the accused; they must not converse with each other concerning the trial. All questions must be put in writing, and the testimony read over for correction before the witness is discharged or withdraws. Any member of a court, the judge-advocate or recorder, can be a witness for either prosecution or defense. When the senior member is called, the next in rank administers the oath. When the judge-advocate takes the stand, the senior member swears him, and he may record his own testimony if there be no clerk. A member called as a witness is not thereby disqualified for the duties incident to his membership, including those in regard to the admissibility of questions put to himself. A witness for the prosecution may also be called for the defense, and need be sworn but once in each case. A court-martial can call witnesses not previously summoned by either side, and this even after both have closed their case. The accused person is entitled to a list of the witnesses to be presented against him, and to have such as are essential to his proper defense summoned. His affidavit can be required as to the materiality of a witness, and he can, at his own request, but not otherwise, be sworn as a competent witness. His failure to so request is not to create any presumption against him (act approved March 16, 1878). See COURTS-MARTIAL, PROVOST-MARSHAL.—*H. C. Cochrane, Captain U.S.M.C.*

Wittee-wittee. A fish-hook of mother-of-pearl, with hair-bait on it, made in the Pacific Islands.

Woare (*Eng.*). An old name for sea-weed. A beach- or shore-margin.

Wolf, or Wolf-net. A kind of fishing-net.

Wolf-fish. The cat-fish, or *Anarrichas lupus*, a fish 2 to 3 feet in length, with large teeth. Also called *sea-wolf*.

Wongs (*Eng.*). Same as *wishes*.

Wood, William Maxwell, Surgeon-General U.S.N. Appointed from Maryland, May 16, 1829; entered the service as assistant surgeon. Commissioned as surgeon, 1838; steamer "Poinsett," Home Squadron, 1838–42; served at that time in co-operation with the army in the Seminole war; Naval Station, Baltimore, 1843; fleet-surgeon, Pacific Squadron, 1844–46; in this period he rendered the service referred to in the

following official documents. Commodore Sloat, commander-in-chief of the Pacific Squadron, writes him: "I am most happy to acknowledge the very important services you rendered the government, and the squadron in the Pacific, under my command, at the breaking out of the Mexican war. The information you furnished me at Mazatlan, from Guadalaxara (at the risk of your life), was the only reliable information I received of that event, and which induced me to proceed immediately to California, and upon my own responsibility to take possession of that country. I have always considered the performance of your journey through Mexico at that time as an extraordinary feat, requiring great presence of mind and address. How you escaped from the heart of an enemy's country and such a people has always been a wonder to me, and has been so characterized on all occasions." The chairman of the Naval Committee of the Senate commented on his valuable services as follows: "Every intelligent mind must at once appreciate the importance of the service which you have rendered the country, and your personal hazard in traveling through the heart of the enemy's country, communicating with your military superior, and furnishing him with the sole and otherwise unattainable information upon which he based the acquisition of California. The importance of this acquisition can best be estimated by asking ourselves, What would have been our national position in the Pacific and upon our Oregon frontier had Great Britain, instead of ourselves, acquired permanent possession of it? I have always contended that its acquisition constitutes one of the navy's strongest claims upon the gratitude of the nation, and this chapter in its history, furnished by your own service, but strengthens this conviction." Receiving-ship, Baltimore, 1847–48; steamer "Michigan," on the lakes, 1850–51; Naval Station, Sackett's Harbor, New York, 1853–55; fleet-surgeon, East India Squadron, 1856–58; during this service, taking part in the Chinese war, and, on board the flag-ship, participating in the brilliant capture (by Commodore Armstrong and the late Admiral, then Commander, Foote) of the 4 forts on the Canton River; steamer "Michigan," on the lakes, 1859–61; fleet-surgeon, North Atlantic Blockading Squadron, during the Rebellion; participating, on board the flag-ship "Minnesota," in the first battle of ironclads,—that of the "Monitor" with the "Merrimac" and other vessels of the Confederate squadron, in Hampton Roads, also in the capture of Sewell's Point; Baltimore, 1866–67; president of the Examining Board, 1868; chief of Bureau of Medicine and Surgery, 1870. Retired, 1871; died, 1880.

Wood. To take in wood. To run a gun out against the side of the port, port-sill, or waterways. Wood has universally been used in the construction of ships, but is fast being replaced by metal. (See Ship.) Various kinds of wood are used in the construction of a ship, and many of the more expensive and ornamental kinds are used in the interior decorations of steamers, yachts, and even of men-of-war. The following are the chief woods used in ship-building: pine, fir, larch, cedar, ash, locust, elm, red willow, walnut, acacia, gum-wood, greenheart, cocoa-wood, lignum-vitæ, teak-wood, saul, sisso, peon-wood.

Wood-and-wood. A close union of two pieces of timber. A nail-head, flush with the wood.

Wood-ends. Hood-ends.

Wooden Walls. The fleet; a term originating with the Athenians, but since appropriated by the English.

Wooden Wings. Lee-boards.

Woodlock. A piece put in the throating or score of the pintle above the load water-line, or as near it as possible, to prevent the rudder from unshipping. One end abuts under the lower side of the brace and the other against the score. It is coppered before being put in, and when in place is secured by driving a copper bolt through it into the stock of the rudder.

Wood-mulls (*Eng.*). Thick hose worn by fishermen.

Wood-sheathing. See Sheathing.

Wood-tar. Tar obtained from wood by distillation.

Woof (*Eng.*). The gray gurnard. The weft or cross threads in cloth.

Woold. To wind rope about a mast or yard where it is fished.

Woolder. A bandage. A stick used in woolding. The bolt of a *Spanish windlass.* The handle of a *rope-maker's-top.*

Woolding. The act of binding with rope. The rope used in binding a mast or spar.

Wool-packs. Light fleecy cumulus clouds in a blue sky.

Woolwich, County of Kent, England, and formerly a naval port, is the seat of the chief government arsenal of Great Britain. It stands on the south bank of the Thames, 7 miles E.S.E. of St. Paul's, London, and now included in the metropolis. The dock-yard, the most ancient in the kingdom, has been enlarged of late years, and has some very fine docks; some of the largest ships of the British navy were launched from it. The yard comprises large dry-docks, and a basin 400 feet long by 300 feet wide. The Royal Arsenal, the largest in Great Britain, contains not only the largest stores of all kinds, but it comprises also establishments for manufacturing them, and for constructing gun-carriages and preparing ammunition for cannon and small-arms. It is the seat of the Royal Military Academy for the education of cadets destined for the artillery and engineers, and is also the headquarters of the royal horse and foot artillery and sappers and miners, for whom and other corps there are extensive barracks here. Pop. 36,000.

Word. The watch-word.

Worden, John L., Rear-Admiral U.S.N. Born in New York, March 12, 1818. Appointed from New York, January 12, 1835; sloop "Erie," Brazil Squadron, 1836–37; Naval School, Philadelphia, 1840.

Promoted to passed midshipman, July 16, 1840; store-ship "Relief," Pacific Squadron, 1843; special duty, 1845; Naval Observatory, 1846; store-ship "Southampton," Pacific Squadron, 1846–47.

Commissioned as lieutenant, November 30, 1846; frigate "Ohio," Pacific Squadron, 1848–50; Naval Observatory, Washington, 1851–52; frigate "Cumberland," Mediterranean Squadron, 1853–55; Naval Observatory, Washington, 1856; navy-yard, New York, 1857–58; sloop "Savannah," Home Squadron, 1859; Home Squadron, 1860; commanded ironclad "Moni-

tor" in her engagement with rebel ironclad "Merrimac," in Hampton Roads, March 9, 1862. During the action Capt. Worden was injured in the eyes by the explosion of a shell from the "Merrimac" upon the outside of the eye-hole of the pilot-house exactly opposite his eye.

Commissioned as commander, July 12, 1862; commanding ironclad steamer "Montauk," South Atlantic Blockading Squadron; commanded the ironclad "Montauk" in the blockading fleet in Ossabaw Sound, and engaged Fort McAllister, on the Ogeechee River, January 27, 1863, and again, February 1, 1863; attacked and destroyed the rebel privateer "Nashville" under the guns of Fort McAllister, on February 28, 1863; commanded the "Montauk" in the attack made by Admiral Dupont, with the ironclad fleet, on the defenses of Charleston, on April 7, 1863.

Commissioned as captain, February 3, 1863. Capt. Worden was promoted out of the line and received the thanks of Congress for distinguished gallantry in the engagement with the "Merrimac," and in other battles in which he had taken part. Special duty, New York, 1864–66; commanded the steam-sloop "Pensacola," North Pacific Squadron, 1867; special duty, 1868.

Commissioned as commodore, May 27, 1868; superintendent Naval Academy, 1870–74.

Commissioned as rear-admiral, November 20, 1872; commanding European Station, 1875–77; member of Board of Examiners since December 29, 1877.

Work. The product of *force* and *motion* in overcoming resistance; its unit is one foot-pound. To labor or strain; as a ship *works* in a sea. To perform; to operate. *To work ship*, to direct or manage a vessel by sails and helm. *To work the engine*, to put it in motion. *To work a day's work*, to compute the run and position of the ship for a day. *To work an observation, a lunar distance*, etc., to make the calculations necessary to find the latitude, etc., from the observations made. *To work a lunar*, figuratively, to sleep during a conversation; to proceed with effort or laboriously. *To work to windward*, to gain to windward by successive tacks. *To work a passage*, to pay for a passage by doing duty. *To work double tides*, to work three days in two, or to work two tides' work in 24 hours. *To work up junk*, etc., to make over junk, old yarns, etc., into gaskets, foxes, and the like. *Working up*, keeping men beyond hours, or working needlessly, as a punishment. *To work off dead-horse*, to perform work paid for in advance. See POWER.

WORKING-HOURS. In a navy-yard the time from bell-ring to 12, and from 1 to bell-ring. The bell rings at 7 or 7.30 A.M., and at 5 or 6 P.M. On board ship, working-hours are from 8 A.M. to 4 P.M., except during meals.

WORKING-PARTY. A gang of men employed in any specified labor.

Worm. To wind a small rope spirally in the spaces between the strands of a large rope. A rope is wormed before being parceled and served.

WORM. A piece of metallic pipe coiled in the form of a helix or spiral, used in distilling. It is immersed in a vessel of constantly circulating cold water, the vapor entering at one end being condensed before reaching the other.

A helical piece of steel wire with a sharp point, attached to a staff, for withdrawing a cartridge from a gun. A small worm is attached to a gun sponge for the purpose of withdrawing fragments of unconsumed cartridge. A screw-thread. See TEREDO NAVALIS.

WORM-EATEN. Perforated by the ravages of the *teredo navalis*.

WORMING. Small-stuff used to worm a rope.

WORM-WHEEL. A toothed wheel, the teeth of which are acted upon, as a nut, by a short screw or *worm*. It is an imperfect piece of mechanism, as the bearing contact can be only a point.

Wrack. A marine plant (the *Zostera marina*), from which kelp is made; also called *sea-wrack*, *sea-wreck*, *sea-oak*, and *sea-tangle*.

Wrain-bolt. A ring-bolt used by shipwrights to bend and bind the planks in place until they are bolted.

Wrain-staff. A stout piece of wood, fitting into the ring of a wrain-bolt, to tighten it up, and so bind the planks in place.

Wrasse. The *Crenilabrus tinca*, or old-wife. A genera of fish (the *Labrus*), containing some 21 species.

Wreck. To destroy or wreck a vessel. To plunder goods from a wrecked vessel, or to gather stranded goods from the beach. The destruction of, or serious injury to a vessel by a stress of weather, or by being cast on shore, on a rock, etc. The ruins of a stranded or wrecked ship. Goods cast up on land from a wrecked vessel.

Among the ancients, shipwrecked persons and vessels were lawful prize, but toward the end of the Roman empire, better laws protected persons and property. The ancient practice was revived during the Middle Ages, when piracy was common. This practice of selling or killing the persons and destroying the ships was continued down to 1680 in the north of Europe. Early English laws gave wrecks to the king, but by laws passed during the reign of Henry III., goods, if marked, could be claimed within a year and a day. But in the reign of Queen Anne, laws were enacted enjoining all magistrates to summon people to assist in saving wrecked persons, goods, etc., on the English coast, and the establishment of a coast-guard and live-saving service has aided there, as elsewhere, in ameliorating the lot of shipwrecked persons. Superintendents of wreck and receivers of wreck were appointed some years since in England, to look out for them. Wise rules as to their conduct, and also laws as to salvage, etc., have been productive of much good in England.

The number of wrecks is yearly great. From 1793 to 1829, there were annually lost 577 vessels of the English mercantile navy, or one-fortieth of the entire amount. In the 5 years, 1863–67, there were 7646 wrecks and 1873 collisions, or in all, 9519 vessels and 3459 lives lost in the English merchant service. About $12,000,000 and 800 lives represent the yearly loss to that nation alone. In 1874, 1999 sailing-vessels, or 3.5 per cent. of all in the world, were lost. Previous to this, in 1870, 2313 were lost, in 1871, 3426, in 1872, 2682, and in 1873, 2165. In 1873 there were 204 steamers, or 4 per cent. of all, lost; and in 1874, 175, or 3½ per cent. 49,322 vessels were wrecked on the English coast in 25 years

(1855–1880). Disasters to steamers on the line of travel between Europe and America have been frequent. From 1840–78, there were 40 steamers lost and 4362 lives sacrificed. Wrecks occur from causes connected with—1. Weather, as gales, currents, seas, fog, lightning, etc. 2. Defective vessels, compasses, charts, etc. 3. Inefficient officers. 4. Machinery and boilers. 5. Miscellaneous, as accident, fire, collision, leaks, absence of buoys or lights, scuttling, and other causes.

Annual reports of wrecks are now made, and summaries published from time to time, notably by the Bureau Veritas, of Paris, and Lloyd's, in London. The United States Life-Saving Service publishes full statistics for the United States. In 1876, 1281 casualties occurred to American vessels, nearly half being total losses. In 1876–77, there were 85 vessels foundered, 220 stranded, 39 collided, and 178 lost from other causes, making a total of 528 vessels lost, involving the sum of $14,500,000, and 1573 were damaged, worth in all more than $63,000,000. In 1877–78, there foundered 79 vessels, while 231 were lost by stranding, 35 by collisions, and 105 from other causes, besides 1492 damaged; 598 lives were lost, and the value of these vessels was $51,000,000, of which $12,000,000 was lost. In 1879–80 there were 300 disasters, 67 vessels being lost. The decrease was 15.72 per cent. in number, and 16 per cent. in tonnage from one to the other year. November, December, and January are the worst months, and the most wrecks then occur.

Wreckage. Spars, rigging, and other floating wreck-stuff.

Wreck-artillery. Wreck-artillery, or wreck-ordnance, comprises such devices as are designed to establish communication between the shore and stranded vessels by means of a projectile carrying a line from the shore to the vessel, or *vice versa.*

There are two principal methods of effecting this intercommunication,—one by means of a line carrying a projectile impelled by the explosive force of powder contained in a gun or mortar, and the other, in which the impelling force is generated in the projectile itself.

To the former class belong all guns, mortars, and muskets used for throwing line-carrying projectiles; to the latter, belong the several life-saving rocket systems.

The U. S. Life-Saving Service has retained the gun and mortar system.

This government first used the old-fashioned cast-iron eprouvette mortar, throwing a 24-pound round ball; then followed a small number of 3-inch Parrott mortars, which gave way in 1878–79 to the 2.5-inch Lyle gun.

The Parrott mortar was made of cast iron lined with a steel tube. The projectile was oblong, rounded at the front end, and somewhat pointed at the rear end, near which was pierced a hole for attaching the line. When loaded the rear end of this projectile extends beyond the muzzle of the piece.

The Lyle gun and system was devised and perfected by Lieut. D. A. Lyle, Ordnance Department U.S.A., in 1877.

It, like the Parrott, is a development of the Manby system, invented during the early part of the present century. Lieut. Lyle prepared guns of three different calibres,—2, 2.5, and 3 inches; the calibre to depend on the range required and the size of line to be used. All these guns are made of bronze, mounted on wooden beds or carriages strengthened with wrought iron.

The 2.5-inch Lyle gun has been adopted by the U. S. Life-Saving Service, and 200 of them have been made, the greater part of which are in use. The braided linen lines made by the Silver Lake Company, of Newtonville, Mass., is used in this country, as giving the greatest satisfaction for shot-lines. These lines, like all others, deteriorate with the lapse of time when stored, and should be replaced every two or three years, else breaks will occur in firing.

The Lyle projectile is made of cast iron, and is cylindro-ogival in form. A wrought-iron shank having an eye at its rear end is screwed into the base of the shot to which the line is attached. The projectile is fired base first, and is reversed by the strain of the line.

I. *Instructions for Use of Lyle Gun.*—Keep the bore of the gun clean at all times. There is often a deposit left after firing, near the seat of the charge, which prevents the projectile from going entirely down to the cartridge. This deposit should always be removed.*

The projectiles should be kept free from rust. The use of emery-cloth and the application of a little oil will protect the shot from rust.

In loading, always measure the distance from the charge to the muzzle with the ramrod or wiper and apply it to the shot. In this manner the gunner can always tell whether the projectile is fully down or is obstructed by dirt or sand.

If the piece be fired when the projectile is not "home," it strains the gun unnecessarily.

II. *Directions for Firing.*—Having the gun and apparatus on the ground, to prepare for firing:

1. Select a place where the gun and carriage may recoil without striking rocks or other obstructions.

2. Note the position of the vessel to be relieved; her distance from the shore, the direction and approximate force of the wind.

3. Place the gun in position, making allowance for the force of the wind and for the drift of the line.

4. Place the faking-box and line on the windward side of the gun, and two or three feet from it,—not more. The box should be on a line with the muzzle of the gun. Loosen the hasps, invert the box, and incline it to the front at an angle of about 45°.

5. See that the vent is clear by inserting the priming-wire.

6. Wipe off the shot with care, freeing it from dirt and sand.

7. Remove the frame and faking-pins, pressing at the same time gently upon the "false" bottom to keep the fakes in place. Then remove the "false" bottom by lifting it slowly until clear of the box.

8. Seize the end of the line, drawing out just enough to reach to the gun without disturbing the fakes in the box, pass the end through the

* Generally removed by using a wet sponge. In very cold weather, alcohol should be used instead of water to prevent freezing.

eye-hole in the shank and tie two or three half-hitches in it, drawing the knot down close to the eye; then wet about three or four feet of the line.

9. Remove the tompion or muzzle-cover from the piece.

10. Insert the cartridge.

11. Insert the projectile slowly until it rests upon the cartridge.

12. Prick the cartridge with the priming-wire to avoid disturbing the elevation after being given.

13. Set the "combination level" to the desired angle.

14. Place the lower arm of the level lengthwise upon the chase.

15. Elevate the muzzle until the bubble of the level stands at the middle of the tube.

16. Adjust the quoin.

17. Unroll the lanyard and insert the hook in the wire loop of the friction-primer.

18. Insert the primer gently in the vent.

19. Stand clear of the line.

20. Fire the piece.

NOTE.—If any of the fakes should slide from the box to the ground, place the loose line in small fakes not more than 18 inches long in front of the box. The necessity for this operation should be avoided if possible.

Comparison.

Piece.	Weight of Piece with Bed, pounds.	Weight of Projectile, pounds.	Total, pounds.	Extreme Range, yards.
Old mortar	288	24	312	421
3.5″ Parrott	535	33	568	631
3″ Parrott	288	22	310	473
2.5″ Lyle	185	17	202	695
2″ Lyle	89	13	102	477

The weight of the Lyle gun, with carriage, as adopted, is 162 pounds; quoin, 4.5 pounds; projectile, 18.7 pounds; total, about 185 pounds. This projectile carries braided lines, Nos. 3½, 4, 4½, 5, 6, 7, 8, 9, and 10, over ranges varying from 300 to over 600 yards, depending on the size of line, charge of powder, and elevation used.

In 1866 the French adopted two pieces of ordnance, *le perrier* and *l'éspingole*, for projecting lines over shipwrecked vessels. Later, M. Delvigne invented a gun for the same purpose. All these pieces project line-carrying arrows (*flèches*) of wood or iron.

Comparison.

Piece.	Weight of Gun, pounds.	Weight of Projectile, pounds.	Diameter of Line.	Extreme Range, yards.
Le perrier	182.9	11.0	0.177″	355
L'éspingole	44.1	4.4	0.177″	196
Delvigne	44.1	17.6	0.315″	328

M. Delvigne obtains a range varying from 196 to 382 yards, depending on weights of projectile and powder-charge, elevation, size of line, direction and force of wind. He claims cheapness and portability combined, with an equal or better range than that obtained with either *le perrier* or *l'éspingole*.

The English have discarded the clumsy system of Capt. Manby, and now use the Boxer life-saving rocket.

The Boxer rocket consists of two rocket bodies, placed end to end, with a conical cavity in each. A portion of solid composition separates the two cavities, so that the forward rocket is not ignited until the composition in the partition and rear one is consumed. The consecutive ignition of the rockets prolongs the time of burning and of flight, thereby extending the range. The line is attached to a long stick fastened on one side of the rocket. The latter is fired from a stand made for the purpose; the line steadying the flight and tending to prevent its deflection from the plane of fire.

The end of the line attached to the rocket is wet, but that does not always prevent its being burned off by the intense heat of the flame that issues from the vent. In firing, a fuze is inserted in the vent at the rear end of the case, and ignited by means of a port-fire.

The rocket bodies are made of Bessemer metal.

The Germans employ 5- and 8-centimetre rockets for carrying lines over stranded vessels.

These rockets have strong metallic bodies, with pointed heads and tripodal bases, into which the rocket-sticks are screwed so as to be in the prolongation of the axis of the rocket. A chain fastened to the end of the stick extends to the rear, in order to protect the line from the flames of the burning composition. The line is attached to the end of the chain.

They also possess an 8-centimetre anchor-rocket for carrying a line beyond the breakers, to be used in hauling a life-boat through the surf after launching. This rocket carries an anchor-head with four flukes or palms at right angles to each other.

With a fair bottom, the "holding" capacity of this anchor is good.

The German rockets all have a fixed fuze in the prolongation of the axis, which is ignited by a short port-fire called a *pillenlicht*. The rockets are fired from an inclined sheet-metal trough. The elevation is given by a quadrant.

The English, Germans, and Americans all have their shot- or rocket-lines put up in boxes.

The lines are stowed away in tiers of peculiar loops, called "*fakes*," in such a manner that they do not become entangled.

The line is wound or faked upon a frame carrying spindle-shaped pins, that hold the loops in position until conveyed to the firing-point, when the box is inverted, the frame and pins withdrawn, leaving the line in readiness for firing.

The Russians make use of a metallic case-rocket, with a stick screwed into the rear end in the prolongation of the axis. Six holes or posterior vents furnish egress to the gases generated by ignition.

In this system the line is not directly attached to the rocket. A chain is fastened to the line to protect it from the flame; the free end of the chain terminates in a ring that is placed upon a projection on the front end of the stand. The under side of the rear end of the rocket-stick is armed with a strong iron hook, which engages the ring as the rocket leaves the tube, and carries out the chain and its appendant line.

The rocket-tube or stand is mounted on a tripod, and consists of a rectangular sheet-iron tube, placed with one of its diagonal planes in a vertical position.

A graduated brass semicircle on one side, furnished with a clamp-screw, serves to fix the elevation.

Comparison of Rocket System.

Kind.	Weight of Rocket, complete, pounds.	Weight of Stand, pounds.	Extreme Range, yards.
Boxer (English)	17.5	30	540
5 cm. German	15.5	35	404
8 cm. German	42.	35	545
8 cm. German anchor	46.5	35	about 400
Russian	25.5	39	?

The range of all line-carrying projectiles depends on their weight, form, on the weight of the powder-charge or composition, elevation, size of line, direction, and force of wind.

The great advantage of rockets is their portability, but this is more than counterbalanced by their erratic flight, their liability to deteriorate from storage, from the expansion and contraction due to changes of temperature, which loosen the composition from the case, allowing the flames to envelop the whole mass, and producing more gas-pressure than the case can stand.

Again, they are very expensive, which precludes any attempt at extended practice by crews of surfmen.

The Massachusetts Humane Society has adopted for use at their life-saving stations—partially, at least—the Hunt line-carrying projectile. This shot consists of a tin cylinder, with a leaden head cast upon one end. Just above this head is a galvanized sheet-iron band, which surrounds the tin case to give greater stiffness to it, and to prevent upsetting by the shock of discharge. A coil of small line, about 0.12 of an inch in diameter, is inserted in the case, which is closed by a wooden plug having a hole in the centre, through which the line is drawn as the shot describes its trajectory. Four trapeziform pieces of tin, styled "wings," are soldered to the outside of the case, near the rear end, to control the flight.

These wings perform a similar function to the feathers on an arrow. A second coil of line is placed at the firing-point. The line is payed out from the two coils simultaneously.

Among other line-carrying projectiles may be mentioned those of Lieut.-Commander W. M. Folger, U. S. Navy, Capt. Butler, U. S. Army, Capt. Chandler, U. S. Navy, Mr. Tatham, of Philadelphia, Mr. Spencer, of New York, and the Lyle-Emery grapple-shot.—*D. A. Lyle, Lieutenant of Ordnance, U.S.A.*

WRECK-CHART. A chart giving the locality and date of shipwrecks on any coast.

WRECK-CLEARER. A station at quarters, the same as *sail-trimmer*.

WRECKER. One who wrecks ships or causes them to be wrecked by false lights, etc. One who visits or searches wrecks for the sake of plunder. One employed in saving life and property from wrecked vessels.

WRECK-FREE. An exemption from forfeiture of wrecked goods.

WRECKING-COMPANY. A company organized to save ships or their cargoes after wreck.

WRECKING-PUMP. A powerful pump used about wrecks, with large suction- and discharge-pipes.

WRECK-MASTER. A person given charge of a wreck or stranded goods by owners or salvors.

WRECKING-TUG. A boat fitted with special appliances for raising, towing, or clearing a wreck.

Wrench. An instrument for screwing or unscrewing bolts and nuts, or pieces connected by screw-threads. It may be either a solid piece, or lever, fitted to a certain-sized *nut*, etc., or adjustable to different sizes; as, a *screw-* or *monkey*-wrench, or a *key*-wrench.

Wright's Sailing. Same as Mercator's sailing.

Wring. To bend, twist, or strain. *To wring a mast*, to distort it by setting up shrouds unequally, etc., or by any strain about the masthead. *To wring a capstan*, to strain it unduly and twist the parts of it out of place.

WRING-BOLT. See WRAIN-BOLT.

WRING-STAVE. See WRAIN-STAFF.

Wrung-head. See RUNG-HEAD.

Wyman, Robert H., Rear-Admiral U.S.N. Appointed midshipman, 1837; attached to razee "Independence" and sloop "Fairfield," Brazils, 1837–38; sloop "John Adams," East Indies, 1838–40; Brazil Squadron, 1840–42; at Naval School, 1842–43.

Promoted to passed-midshipman, June 29, 1843; East Indies, 1843–46; served in the Gulf during the Mexican war; present at the siege of Vera Cruz; Observatory, Washington, 1848; receiving-ship at Boston, 1849–50.

Commissioned as lieutenant, July 16, 1850; sloop "St. Mary's," Pacific and East India Squadrons, 1850–52; Observatory, Washington, 1853–54; practice-ship "Preble," 1855–56; razee "Independence" and sloop "St. Mary's," Pacific, 1856–59; practice-ships, 1859–60; sloop "Richmond," 1860–61; commanding steamers "Yankee" and "Pocahontas," 1861; "Pawnee," South Atlantic Blockading Squadron, 1861–62; battle of Port Royal, November, 1861; commanding Potomac Flotilla, 1862.

Commissioned as commander, July 16, 1862; commanding steamer "Sonoma" in James River, and "Wachusett" and "Santiago de Cuba," West India Squadron, 1862–63; special duty, Washington, 1863; special duty, Navy Department, 1864–65; commanding steam-frigate "Colorado," flag-ship European Squadron, 1865–67.

Commissioned as captain, July 25, 1866; commanding steam-sloop "Ticonderoga," European Squadron, 1867–69; Hydrographic Office, Washington, 1869–70; in charge of Hydrographic Office, 1871–77.

Commissioned as commodore, July 19, 1872.

Promoted to rear-admiral, April 26, 1878; special duty, Washington, 1878; commanding North Atlantic Station since January 15, 1879.

X.

Xantho. A genus of brachyurous crustaceans, containing numerous species, and existing in all seas.

Xebec. A Mediterranean coasting-vessel from 200 to 400 tons, and carrying from 18 to 24 small guns. It is sharp-built, with far-projecting bow and stern, flat floor, and very convex decks. It has three masts, with the fore-raking forward, and sometimes the others also, and a bowsprit and stern-boom. Square yards are used on the fore and main when the wind is fair, but are replaced by lateen-sails when it is not. Oars are sometimes used. Square topsails are sometimes seen on all three masts.

Xero-potamo. Torrents in Greece, dry at times.

Xiphias. A genus of acanthopterygious fishes, including the sword-fish. A constellation in the southern hemisphere, called also *dorado* and *sword-fish.*

Xugia. The second bank of rowers in a trireme.

Xylogodine. Dittmar's powder, an explosive compound of nitric or sulphuric acid and glycerine cellulose. See EXPLOSIVES.

Y.

Y. Abbreviation for *why* in the U. S. General Service Signal Code.

Yachts and Yachting. 1. *Derivation.*—Webster defines the word yacht to mean "a light and elegantly furnished vessel, used either for private parties of pleasure, or as a vessel of state to convey princes, etc., from one place to another; a sea-going vessel used only for pleasure-trips, racing, and the like." The word "yacht" is unquestionably to be traced to the old Danish "jagt," implying a vessel for the chase of others, such as the capture of pirates and smugglers. As a matter of course, speed was in them an essential, and the same property being largely aimed at in pleasure-craft, the original meaning of the word was gradually widened until the interpretation given by Webster became generally accepted. While many vikings of the olden times indulged in pleasure-cruising, combining a voyage of exploration with the adventures of the chase, or the excitement of a piratical descent upon an enemy's coast, the first authentic record we have of any vessel built and owned especially for the purposes of yachting dates back to 1588, when the "Rat of Wight" was launched at Cowes, England. From that day the sport may be said to have firmly planted itself in the favor of the English people, and the town of Cowes has ever since maintained the first position among the yachting ports of the world. From the original little "Rat" has grown a vast fleet of fine vessels of all types and sizes, representing in the aggregate millions of money, and employing a large body of men in the capacity of sailors and attendants. In 1661, Charles II. sailed the first regular match on record, on the river Thames, from Greenwich to Gravesend, his competitor being his brother, the Duke of York. In the words of a historian of the times, "the king lost it going, the wind being contrary, but saved stakes in returning, his majesty sometimes steering himself." From this the modern critic will conclude that the king's yacht was not good for much in windward work, but had the advantage of the opposing craft on the free run home. Charles II. and his brother may fairly be rated as the first "Corinthians" in history, for they handled the tiller and evidently skippered their yachts themselves. The construction of yachts became common enough in the 18th century, and their numbers had increased so rapidly in and about Cork Harbor, that the first club, or organized association, to promote the sport was founded in 1720, under the title of "Cork Harbor Water Club." Cowes followed in 1810, the club containing some vessels of considerable tonnage, in which the features of the man-of-war were more or less closely imitated, while the older boats of the Cork club partook of the nature of open harbor craft, being shaped something like a walnut, with the mast amidships and the bowsprit pointing skyward. The pastime soon became fashionable, being patronized by the Duke of Clarence, afterwards George IV. The Royal Yacht Club,

in reality the parent of all similar institutions of modern times, was organized and adopted a seal in 1812, at which time the number of legitimate yachts reached about 50, belonging almost exclusively to noblemen and functionaries of the government. The number rapidly grew, until in 1850 it is estimated there were 500 afloat. From all sorts of nondescripts, racing had gradually developed something like a recognized type or standard in the prevalence of the "cod's head and mackerel tail" form, as the bluff bows and sharp sterns of the day were denominated. The largest athwartship section, or in technical parlance, the midship section of these yachts was full and round bilged with a moderate angle of dead-rise to the floor, the whole being copied from the carrying vessels of the times. Even at this early period the rules by which tonnage was calculated began to exert a powerful influence upon the shape of the hull, and as measurement for racing purposes has really had more to do than any other cause in directing the course of builders and modelers, it will be well to follow its influences closely. In order that large and small vessels might be raced together with some degree of fairness a certain amount of time was granted by the former to the latter, depending generally upon the length of the course sailed and the difference in size. To obtain a gauge of size the first rule applied was that in vogue in the contemporary commercial marine.

Tonnage was measured by multiplying together the length on the keel and the breadth and the depth, and then dividing by 94, the result being assumed as the actual contents of the vessel expressed in tons. Owing to the difficulty of measuring depth, and the general conformity thereof to one-half the vessel's breadth, the latter fraction was substituted in the rule in place of the actual depth. It worked well enough as long as constructors were inclined to follow such proportions. Yacht-builders, however, were not slow to discover the weak points of the tonnage rule, and, appreciating the advantage of size in relation to speed, they reduced the beam and increased the depth in successive models, obtaining by such stratagem a large boat which would nominally be of small tonnage. The success of such craft in overpowering their smaller rivals rated at the same, or even a larger figure, soon made the narrow and deep hull quite the fashion, all sorts of virtues being imputed to it, the supposed virtues having no other foundation in truth than in the additional size smuggled in at a race and the increased momentum in a seaway. Nor did the builders stop with the modifications indicated, but they gained still further advantage by giving a violent rake to the stern-post, and an overhang to the stem, so completely circumventing the object of measuring the length on keel, that yacht clubs were finally compelled to stretch their tape-line on deck from stem-head to stern-post instead. In later years, the persistent evader of the spirit of measurement crooked or elbowed the upper part of the stern-post to save what he could on the length, and finally took to moving the post bodily forward, until his sharp practice was at last checkmated by measuring for length on the line of flotation itself. These alterations in the rule produced in succession the various types of yachts which, in their day, were regarded as invincible and as the highest development of naval architecture, though being, as a matter of fact, simply more or less successful evasions of equity, and owing their fame to untaxed superiority in size more than to anything else. Wanhill, of Poole, gained fame in this way between 1840 and 1850, when great depth and dead-rise obtained such prominence by the performance of his "Cygnet," "Heroine," and others, while Harvey, of Wivenhoe, in 1852, then an apprentice in his father's yard, carried the rake of the stern-post to the greatest extreme, in rebuilding the well-known little cutter "Kitten," of 10 tons, now owned in Boston, Mass. The amount of experimenting and innovation incidental to the manœuvring for untaxed size was not entirely without its advantages to naval architecture. A great deal was added to our store of practical knowledge concerning the behavior of vessels of various kinds. While Scott Russell and others were engaged in formulating the theories of the science, yacht-builders contributed their quota in the way of actual experiment. The most notable influence upon the design of vessels for speed was produced by the arrival of the schooner "America" at Cowes, July 31, 1851. She may be said to have fairly opened the eyes of the world to the fact that America was rapidly assuming a leading rank as a maritime nation, and that the greatest pitch of perfection in model was to be found in the ports of the new continent, and not in those of the old. The "America" was built in 1851, by George Steers, for Mr. J. C. Stevens, commodore of the New York Yacht Club, then a young, and the only organization of the kind on this side of the Atlantic. The schooner was 87¼ feet long on the load-line, 22.2 feet beam at the same line, and had a mean draft to the rabbet of 8.2 feet. Her load displacement in cubic feet was 5133.2, or 146.6 tons. She carried 45 tons of ballast; her hull weighed 60, and the equipment 41½ tons. The area of her 3 lower sails was 5263 square feet. After her voyage across, made under short spars, she was refitted at Havre, and on the 22d of August, 1851, started in a race for the Royal Yacht Squadron cup around the Isle of Wight, beating the entire English fleet out of sight. Subsequently she defeated the "Titania," and was then bought by Lord de Blacquiere. Under the management of her English crew she was beaten by the "Arrow" and "Mosquito," but in turn vanquished the Swedish schooner "Sverige," a smart vessel, built on much the same principles as the "America," but lacking the latter's beauty and harmony of lines. The great victory of the transatlantic visitor caused a profound sensation among the nautical public.

She differed radically from the English boats of the day in having a long, fine, and hollow entrance, with very easy section-lines to her after body, and carried the greatest breadth, as well as her centres, abaft the middle. In short, she was a "cod's head and mackerel tail," but turned end for end, while the Englishmen had nothing better to pit against her than the round-bodied, bluff-bowed old boxes belonging to a bygone age. The "America's" sails were cut so as to set flat on the wind, while in the English fleet the old "square-riggers" idea of bellying canvas still held sway. In a few words, the English yachtsman was behind the age. Nor was he long in discovering this, for he set to work energetic-

ally remodeling and altering, with the form of the "America" always in view. From the date of her visit the birth of the really modern period of yachting may be reckoned. "Wave-lines," and "wave-line" areas of the cycloidal family, became the standards of the new departure, to which it may be said all the successful yachts of the present era closely conform. The "America" was, however, by no means the first representative of the new departure in design, though the prominence she achieved by her victory at Cowes gave a greater impetus to the new order of things than anything else could have accomplished. Steers himself had built a number of successful yachts on the same principles prior to the construction of the world-renowned schooner, and others in Europe had already discerned the true path, and had put the wave-line theory into practice. The most notable example abroad of the early introduction of the long and hollow bow and cycloidal design is the cutter "Mosquito" of 40 tons. She is also the first authentic iron yacht of note. Both Mr. Ditchburn and Mr. Waterman claim the honor of originating the plans from which the cutter was built by Mare, of Blackwell, in 1848. Her record as a racer is a brilliant one, and upon one occasion she gave a good account of herself in a match with the "America." Like that schooner, the "Mosquito" is a vessel of extraordinary beauty and fairness in all her proportions, and it is an open question whether at this late day anything superior or even equal to these two representative yachts has ever been launched. It is quite certain that we have nothing to equal the "America" on this side of the Atlantic, either in point of speed or seaworthiness, and were it not for the faulty tonnage rule in vogue in England, it is doubtful whether anything of superior mold to the "Mosquito" has left the builders' hands across the sea. The tonnage rule places such a heavy premium upon narrow boats, that the comparatively beamy "Mosquito" would be rated so much in excess of her real size as to seriously interfere with her chances in a race with the lean English cutters of to-day. Both these yachts are remarkable, because at one jump their projectors gave to the world two craft which have been standards ever since, and two craft which must certainly be counted nearly faultless in form. Mechanical structure and contrivances have undergone changes and improvements, details have been perfected, but in form—in the principles of design exemplified by the "America" and the "Mosquito"—the world has not advanced an iota. The efforts of later years have been to equal, rather than to surpass them. Since 1851, a great refinement in model, canvas, gear, and ballasting of the world's yachting marine has taken place in consequence, especially in England; but the old Thames rule, now renovated in some details, and disguised under the name of Yacht-Racing Association rule, still has such an effect upon the form of yachts, that the representative boats of England and America have become widely divergent in all their chief characteristics. Fortunately, actual experiment has shown that the peculiar type of vessel fostered by the Yacht-Racing Association rule is not incompatible with the essentials a rough-water yacht should possess, and if it circumscribes the latitude of the designer, it, at all events, does not hinder the production of a style especially suited to the wants and necessities of British waters; the worst which can be urged against the modern English cutter being her great first cost, as lead ballast has in them become a necessity. In America, on the other hand, through the custom of measuring by length only, without regard to the other two cardinal dimensions, the builder has to an equal extent been driven to the adoption of one set form, from which he finds escape impossible. The size he needs must be sought in those directions which are not taxed in racing. Hence the prevalence, even among our large yachts, of great breadth of beam, and the consequent shallowness of hold and flat floor. While we have not advanced in the least in form, the Englishman may be said to have created, if not invented, an entirely new style of craft, many features of which we are now tardily beginning to copy. If to us the Englishman owes his conversion from the ancient faith of bluff bows and bellowing sails, so have we in turn learned from him the value of ballast on the keel, of easy forms and large displacement for work in open water, and from him we have taken the handy rigs of the cutter and yawl, which have of late come into popularity. From the small nucleus of 500 yachts 30 years ago, the fleets of the world have grown with great strides, until those of Great Britain alone number 3000 sail and over, "Lloyd's Yacht Register" for 1880 showing more than 2500 of which statistics have been gathered. The following table will give an idea of the classification, according to size and rig, of this fleet up to 1878:

Number of Yachts.

	1850.	1864.	1878.
Under 5 tons	4	52	160
5 tons, not exceeding 9 tons	50	137	300
10 " " " 19 "	127	207	403
20 " " " 29 "	85	113	180
30 " " " 39 "	59	69	96
40 " " " 50 "	41	44	89
50 " " " 60 "	27	47	50
60 " " " 80 "	40	59	88
80 " " " 100 "	15	36	60
100 " " " 150 "	33	53	87
150 " " " 200 "	9	30	48
Above 200 tons	10	15	40
Steam-yachts	3	33	282
Total	503	895	1883

According to Rigs.

	1850.	1864.	1878.
Cutters	372	574	754
Schooners	76	207	328
Yawls	45	54	328
Other rigs	7	27	25
Steamers	3	33	282

Tonnage.

	1850.	1864.	1878.	1880.
Average	44	44	47	45
Gross tonnage	22,141	39,485	89,420	120,000

This fleet in 1880 employed no less than 12,000 hands regularly under pay, and represents a value of nearly *ten million* dollars.

If we turn to America, we find even a more rapid development of the sport, considering the want of leisure and wealth prevailing in a new country.

Statistics relating to the earlier days are of

course very meagre, but enough can be gathered from the following compilations to see that if the advance in the future keeps pace with that of the past decade, we may soon expect to surpass Great Britain in the number of our yachts, though it will be a long time before we can out-ton the average of her fleet. At the close of "the war," in 1865, there were only 10 organized clubs in America, with hardly 800 members. In 1879 we find 100 organized clubs, with a membership of over 7500. The fleet in 1865 consisted of about 200 cabin yachts and 150 "open boats." In 1879 it had grown to 530 cabin yachts of which records could be obtained, and the fleet has since then been still further increased by new additions to fully 600. In 1879 they were classified as follows:

150 schooners, average	52 tons.
308 sloops, "	14 "
40 steamers, "	35 "
20 yawls, "	20 "
10 cutters, "	25 "
Total, 530	Average, 27 "

In addition, there are now some 500 small yachts and open boats under 5 tons, of the jib-and-mainsail and cat-boat varieties, and also a score of catamarans. During the past year the popularity of the cutter and yawl has developed, and the leading clubs have from three to a dozen each of the new-fashioned rigs. The total tonnage for 1880 may be set down as about 18,000 tons, employing 2000 hands, and representing nearly $1,500,000. The racing statistics subjoined serve to give an idea of the extent of that phase of the sport and the activity of recent years:

Classification.	1875.	1878.	1879.

2. *Types of Yachts.*—Of late there seems to be a tendency among architects and owners in America to devise what may be termed a "happy mean" between the extreme types representing the customary practice of Great Britain and this country. The principal characteristics of the two varieties, and the possibility of striking the most satisfactory results by adopting something about half-way between them, can be gathered from the following. The British yacht is the outgrowth, on the one hand, of the old Thames rule of measurement, and on the other, of the demand for capable qualities of all kinds in rough water. These requisites have been successfully attained in the most recent specimens, such as the famous "Vanduara" and the "Samoena," both of 90 tons, the "Jullanar" and "Florinda," of 100 tons, and among the smaller classes by such splendid performers as "Neva," "Britannia," "Vanessa," "Louise," "Madge," and down to the beautiful little 5-ton cutters "Freda," "Coralie," "Vril," and a host of others. They are all yachts of great length and depth in proportion to their beam, and have much of their ballast in lead on the keel. Their sea-going qualities are of the highest order, and leave little to be desired. They are fast in very light winds and in heavy weather. They are uncapsizable, having their greatest range of stability when on their beam-ends, require only small rigs, are easy on their helms, sure in stays even in rough water, and under complete control. The objections to such boats may be counted as their comparatively great first cost, their excessive heeling, and their large draft of water. None of these objections are serious, and upon consideration lose much of their force. Their great cost arises from the universal excellence of their build, such as the use of copper and through fastenings, the best material, hard-wood trimmings, a very complete inventory in all departments, and the prevalence of lead as ballast. As the latter is becoming the metal generally used in all first-class yachts, even in America, the expense attaching to British boats arises rather from their superior quality than from considerations of model. Their excessive heeling takes place only in strong lower-sail winds; in light weather and when reefed down the objection disappears, for they are stiff enough for comfort under such circumstances. In the matter of draft, practice proves a liberal amount an obstacle only in isolated cases or under special circumstances. The normal condition of boats supplied with centre-boards, ostensibly to obviate large draft, is with the board down, in which condition they actually draw more water than if supplied with a keel. There are times when the option of raising the board is a decided advantage, but the occasions for so doing are rare enough to question the advisability of foregoing the advantages inherent to the fixed keel, including the low position of the "outside" ballast, better performance in open water, stronger construction, and increased room in the accommodations,—an item of importance in boats of moderate tonnage. Concerning speed, it has by no means been proven that centre-board yachts are faster than keel vessels, though the former have generally been developed in form to a higher degree than the latter in America, and have created the impression that the centre-board is an essential to high speed. The schooner "America" in competent hands, although a keel, is still without a peer in the centre-board fleet, and enough races have been sailed between the best of the two classes to cause professional men to question the supposed superiority of the board itself. The following tables show in a marked manner the change in form which has been going on in the British fleet, and how the old round ships have been displaced by the modern craft in compliance with the pressure of measurement and the rough-water qualities the yachtsmen abroad value so highly:

The Old British Fleet.

* 25 tons was in lead on the keel.
† 2½ tons lead on keel.
‡ 2¼ tons lead on keel.
§ 1 ton iron on keel.

In American practice, we find the wide, light-draft boats still prevailing, although a gradual change in the direction of more depth has been steadily showing itself. Owing to the fact that yachting on this side of the Atlantic had its origin in river-sailing, and since much of our sailing is still done in sheltered waters, it is quite natural that the prevailing type of boat should have been largely influenced thereby, and that sea-going qualities in hull and rig should have been neglected. With the accumulation of wealth and greater leisure comes the desire to extend our cruising-grounds and to undertake more or less distant voyages, and a modification of model is taking place in response. The chief recommendations of the wide and shallow boat are her great stiffness and consequent comfort, cheap first cost as long as we remain satisfied with iron ballast, quickness in stays, great speed in strong, lower-sail winds in smooth water, and last, the option of raising or lowering the centre-board as before alluded to. The objections to such boats are serious and numerous. They are very hard on their helms, easily capsized in a squall or through want of close attention; they have little deck-room owing to the almost universal presence of a raised house over the cabin to afford head-room below, and to the length of which the available accommodations are limited in yachts of less than 50 feet. They require large sails to drive them; they are not reliable in stays in rough water, and they are exceedingly bad and violent sea-boats. In light airs they are slow, while in a seaway they are leewardly, and cannot work to windward unless the seas are long, easy swells. Owing to their large draft with the centre-board down, there is much danger of twisting the latter by "sounding" in shoal water, and the trunk or well containing the board is liable to give trouble on account of leaking when strained. The boats are expensive in wear and tear, and not long-lived without heavy scantling and kneeing, deducting materially from the amount of ballast, sails, and speed. The sloop-rig, consisting of a large mainsail and jib, is not adapted to yachts of fair tonnage, its unhandiness involving large crews and being productive of danger in bad weather; its toleration is to be traced to the prevalence of river-sailing in small

boats in years past. As an escape from the sloop's unhandiness the American yachtsman has always exhibited great partiality for the schooner-rig, thereby sacrificing much of his boat's weatherliness and speed to handiness In medium-sized yachts, of 40 to 70 feet, the adoption of the cutter- or yawl-rig gives the necessary control over the canvas and insures the best sailing results. The number of cutters and yawls has increased at a rapid pace during the past two years, the yawl having almost entirely superseded the sloop in the San Francisco Yacht Club. These rigs require only to become better known to be appreciated and adopted in place of the sloop and small schooner, neither of which is appropriate to the work in view. As far as practice has developed there is no difference in speed between the cutter- and sloop-rig, the better disposition of the weights in the former, and the superior facility of handling and trimming the double head-sail, more than counterbalancing the presumed advantage of having all head-sail in one. The yawl is slightly inferior in speed to both, but more efficient again than the schooner. It is, in fact, a cross between the two. For cruising it is to be recommended as a safe and snug rig, always leaving the yacht under control while shortening or making sail, and offering the greatest inducements to short-handed crews. There seems little doubt that a well-considered average between the customs of the two leading maritime nations would lead to the best results. Both countries have gone to extremes in opposing directions so far as model is concerned, owing to the special causes already cited. A design seeking a compromise, in which the points of excellence of each type are represented and liable to none of their weaknesses in as great a degree, will supply the demands of the great majority, who value "all round" qualities rather than great perfection in one direction at a sacrifice of equally as important requirements in another. If the ideal design be supplied with beam enough to obtain fair stiffness, or statical stability, in conjunction with a keel and low ballast, the principal advantage of the sloop has been incorporated with the keel cutter. On the other hand, the excessive draft of the latter, her narrow cabins, "tenderness," and all lead ballast disappear without interfering with the acknowledged excellence of good depth and moderate beam in open water-work. If the fine lines, skillful and handsome form of the American yacht, can be engrafted upon a moderately beamy cutter, the yachting world will be a decided gainer. In British waters the peculiar measurement rule stands in the way; in America, only prejudice and the custom of confining ourselves to sheltered waters near home. Both are giving way; the venturesome yachtsman learns by experience that his shoal, flat-bottom craft, however convenient for harbor-work, is not to be trusted at sea, and his influence is henceforth exerted in behalf of the modifications which have recently taken root and produced some of the most satisfactory yachts afloat. The fleet of the future, on this side of the Atlantic, will probably take shape accordingly, and boats of wholesome dimensions and sailor-like rigs will displace the make-shifts of the day. The prevailing type at present can be gathered from the tables on pages 859, 860.

Racing boats like the "W. T. Lee" carry 50 to 75 bags filled with sand, weighing 50 pounds each. In the Delaware racing boats, such as the "Cohill," the crew "lay out" to windward by means of rope-spans.

In general, owing to the diversity of model and scantling, and the habit of over-sparring, the ballast carried by American yachts varies very much in boats of the same tonnage. The wide boats with little dead-rise weigh much more than those of the same tonnage, but of less beam and more depth. This and their excessive stability of form causes them to sail with very little ballast. Such boats are treacherous in rough water or squally winds, and are rapidly going out of favor.

3. *Steam-Yachts.*—In yachts propelled by steam the naval architect is freed from the necessity of supplying excessive stability, and the problem of successful design becomes much simplified in consequence. As might be expected, such vessels take on a great variety of form according to the wants they are to supply. The steam-cruiser becomes an elongated box, with the ends more or less fined away and the bilge rounded off; the river-yacht, a light cockle-shell with flaring sides, a sharp entrance and fine run, her lack of depth being made good by superstructures of joiner-work; and the high-speed launch assumes the form of a lean-ribbed racer with knife-like entrance and attenuated after body, the entire displacement being devoted to the weights of hull and driving-power. In all these yachts the engineer legitimately supplants the architect to a great extent, and the sailor gives way to the stoker. No strict classification of steam-yachts can be made, one type blending into the other as we pass from river-craft to those designed to navigate the open sea. For small boats the usual style of construction with wooden frames and skin still prevails, although composite build, iron frames with wood planking, has been successfully introduced where lightness and toughness becomes a prime necessity in the pursuit of high rates of speed.

Practical Construction.—Owing to the diversity of the work expected from yachts, much latitude is permissible in practical construction. Generally too much stress is laid upon the importance of heavy scantling, while the durability of the material, its capability of taking and holding fastenings, and especially the character of the latter, are too often overlooked. Where little "through" fastening or clinching and heading is done, the material should be proportionally longer. If much clinch-work is made use of, scantling may be considerably reduced, the structure becoming light and tough, and a unity throughout. The weight thereby saved will be so much more to go to account of ballast, and a larger sail spread, and speed. Oak, hackmatack, chestnut, and Oregon fir are used for frames; cedar, oak, white and yellow pine for plank and ceiling; white pine for decks; oak, mahogany, and walnut for combings and fittings; locust for bitts, pin-rails, and stanchions; and sometimes teak for waist and hatches. Knees are of oak and hackmatack, also of chestnut. The kinds of wood vary much, according to what the local markets afford. Anything that is to give form, hold fastenings, or stand chafe and wear, should be of hard wood; the rest may

I.—Inverted engines.
The "Miranda" is one of Thorneycroft's high-speed launches. Her engines indicate 11 horse-power with 300 revolutions and a speed of 11 miles. With 500 revolutions they indicate 42 horse-power; speed, 16 miles. With 600 revolutions they indicate 71 horse-power; speed, over 20 miles.

be of the pine family, but should be free of sap. Spars are of spruce or Oregon pine. Always build under cover when possible. All surfaces exposed to the weather should be well painted, except decks, combings, and rails, when kept "bright" for stylish appearance. They should be scraped or holy-stoned often enough to prevent the gathering of fungus or weather-eaten spots, as they rapidly extend. A good plan is to whitewash or coat with Stockholm tar all inaccessible parts inside, and especially the skin which is to receive the iron ballast. If the wood has not been well seasoned, especial means should be provided for the circulation of air between the frames by supplying automatic valves in the covering-board, or boring holes in the clamps between the beams. Iron coming in contact with salt water should be galvanized, and an extra allowance made to its thickness where strength is an object. In general, all the rules which apply to ship-building should govern the practice of yacht-builders. It may be said that yachts as a class are too lightly and carelessly built, and much too lightly and negligently rigged and incompletely fitted. The following rules will serve as a guide, though they may be departed from according to the service a yacht is intended for. Where a vessel's form is abnormal, allowances must be made in proportion to the increased strains. In long and narrow boats, greater longitudinal strength must be provided, and in wide, flat-floored boats, additional athwartship strength, and ties must be introduced for stiffening purposes.

* The "Bretagne" is sparred as follows: foremast, deck to hounds, 46 feet; topmast, 37 feet; mainmast, deck to hounds, 48 feet; topmast, 37 feet; mizzen-mast, 48 feet; yards, 60, 46, and 30 feet; bowsprit outboard, 15 feet.

C. I.—Compound inverted engines.

Patent Coil.—The Herreshoff coil boiler weighs one half and consumes one half the coal (for power developed) of the ordinary locomotive boiler, and is rapidly displacing the latter in yachts. It requires only a few minutes to raise steam. See New York *Forest and Stream*, vols. xiv. and xv.

m.—Mean draft loaded with 7 persons on board.

When ballast is carried on the keel, the latter is made larger, both from considerations of strength as well as to obtain the room required for the weight. Some English yachts carry nearly all their ballast on the keel. Thick keels have not proven a hindrance to speed. The ballast is held to the keel by through bolts with nuts and washers. A new plan is to cast the floors of iron or lead, thereby bringing the inside ballast as low as possible.

Wooden Yachts.

Iron Yachts.—According to Lloyd's rules, the following table is based upon the proportions as well as the tonnage of the yacht. The scantlings are for boats of not unusual form.

The number for regulating sizes of frames, reversed frames, and floors is obtained by the addition of the half beam amidships, the depth from upper part of keel to top of upper deck beams, and the girth of the half-midship frame measured from centre line at top of keel to the upper deck stringer-plate in feet.

The number for regulating sizes of keel, stem, stern-post, keelson, and outside plating and deck, etc., is obtained by multiplying that which regulates the size of frames, etc., by the length of the vessel.

Iron Yachts.

Number for Frames and Floors.	Angle-iron Frames.	Reverse Frames.	Floors.	Numbers for Keel, Stem, Post, and Plating.	Spacing of Frames.	Keel, Stem, and Post.	Outside Plating.	Middle Line Keelson.	Thickness Upper Deck.	Rudder-head.
20	1½×1½×¼	....	7×¼	1100	18	4½×⅝	$\frac{5}{32}$	....	1¾	1½
25	2×1¾×¼	1½×1½×¼	9×½	1700	18	4½×⅞	¼	....	2¼	2
30	2¼×2¼×$\frac{5}{16}$	2×1¾×¼	11×¼	3100	21	5¾×1⅛	⅜	7½×⅜	2½	2⅞
40	3×2½×$\frac{5}{16}$	2½×2¼×¼	14×$\frac{5}{16}$	5100	22	6½×1¼	$\frac{7}{16}$	8½×$\frac{7}{16}$	2¾	3½
48	3×2¾×⅜	2½×2½×$\frac{4}{16}$	16×$\frac{5}{16}$	6800	22	7×1⅜	½	10×½	2¾	3⅞

These examples are of actual steam-yachts of 25, 50, 100, 250, and 400 tons respectively.

On the two smaller ones angle-irons are worked over the floors in place of a keelson. The larger ones have also angle-irons on upper and lower edge of the keelson-plate, besides deck-stringer and tie-plates. The garboards and sheer-strakes are somewhat heavier than the side plating. The plating tapers at each end. Up to the number 3500, reverse frames need be fitted only under ballast, engines, and boilers. From 3500 up to 6500, reverse frames are required on every frame, and should run well up to the turn of the bilge. If over 6500, every other one must be run up to the gunwale. Bulk-heads are made of ¼ inch iron, and stiffened with angle-iron. In steel yachts a deduction of 10 to 15 per cent. may be allowed, but is not advisable in open-water yachts, as the thin plating is liable to buckle and corrode through. The size of beams depends upon the beam of the yacht. For 8 feet beam angle-iron is used, $2\frac{1}{2} \times 2 \times \frac{1}{4}$; for 12 feet beam, $3\frac{1}{2} \times 2\frac{1}{2} \times \frac{5}{16}$; for 15 feet beam, $4\frac{1}{4} \times 3 \times \frac{6}{16}$; for 20 feet beam bulb-iron takes its place, $5 \times \frac{5}{16}$, with double angle-irons at the upper edge, $2 \times 2 \times \frac{5}{16}$; for 25 feet beam, $6\frac{1}{4} \times \frac{6}{16}$ bulb-, with angle-irons $2\frac{1}{2} \times 2\frac{1}{2} \times \frac{5}{16}$. Rivets for ⅛ plate are ⅜ inch in diameter; for ¼ plate, ½ inch; for ½ plate, ¾ inch. The corresponding spacing should be 1½, 2½, 3½ inches between centres for water-tight work. Double those distances nearly for ordinary work. The same rules and tables apply to iron sailing-yachts.

Anchors, Chains, and Hawsers.

Approximate Length on Water-line.	Number of Anchors.	Best Bower in Pounds.	Diameter of Chain for Same.	Circumference of Suitable Hawser.
25	2	50–75	$\frac{9}{32}$	.....
34	2	80–100	$\frac{6}{16}$	4
46	2	135–150	½	4½
60	3	200–225	⅝	5
80	3	375–425	$\frac{11}{16}$	6
100	4	625–700	$\frac{13}{16}$	6½

For steam-yachts deduct 20 to 33 per cent., the greater difference being between small yachts.

Spars and Sails.—The masts of sloops, cutters, and yawls, when supplied with a single head-sail only, are stepped from 28 to 33 per cent. of the load-line from the forward end. When rigged with double head-sail, the mast is stepped 40 to 45 per cent. from forward, to allow foot enough to the fore-stay-sail. In schooners the position of the masts varies much, the object to be kept in view being the balancing of the centre of the sails, and the centre of the immersed longitudinal plane. The former, known as the "centre of effort," should be placed slightly forward of the latter in round-bodied boats with flare to the bows, and in narrow, long-bowed, deep boats, it may be placed almost directly over the centre of lateral resistance. This plan of arranging sails works very well in vessels which are not extravagant in form. Practical men term the operation "hanging" a vessel, and often obtain an excellent balance by the thumb rules derived from long experience. In English cutters masts are stayed about plumb. Some of their schooners have a moderate rake of 1 to 8 or 1 to 10. American sloops have a rake of 1 to 10 or less, and some of our yachts have none at all. Rake is purely a matter of fashion, and has not been found of any practical value, unless in exceptional cases, where lifting power was desired in the sails, or to bring the dynamical moment of the spars farther aft. Masts are given 1 inch in diameter to every 4 feet of length, booms and gaffs 1 to every 5 feet.

Fixed bowsprits of small yachts are made of more or less rectangular section, with the longest side placed transversely. English yachts have running bowsprits, which can be reefed or housed in bad weather, when a small jib is set. Storm-jibs in American sloops are carried out and hooked to an eye-bolt about half-way out on the bowsprit. Fixed bowsprits are objectionable in sea-going yachts unless very short, and are disappearing in such craft. Topmasts should be long, half the length of the mast, and housed when not wanted. Fixed topmasts will serve in small craft intended for river-work only. Sails for yachts of moderate size are made of 10-ounce duck, for large boats of No. 7 and No. 6 canvas, while storm-sails are made of No. 5 and No. 4. The numbers of canvas are regulated by the weight of a bolt or yard. Thus, No. 1 weighs 46 pounds to the bolt of 40 yards; No. 2 weighs 43 pounds; No. 3 weighs 40 pounds, and so on. Bolt-rope should be of the best Riga hemp, the yarns tightly twisted, but the strands not laid up too tightly. It is about 1¾ inches in circumference for head and foot of schooners' sails, and 2½ and 2 inches for luff and leach. For small yachts 1½ to 2 inches, and for sailing-boats from 1 to 1½ inches, a "drawing-string" in the after-seam often taking the place of the bolt-rope on the leach of the mainsail. For storm-sails add 10 or 15 per cent.

6. *Organization.*—Yacht clubs are organized with a board of officers composed of a commodore, vice-commodore, treasurer, secretary, and measurer. To these a rear-commodore is added when the fleet is numerous enough to justify it. The constitution of a club provides for the election of officers,—generally once a year,—specifies their duties, the manner of voting, rules governing the admission of new members, honorary members, life members, meetings, assessments, and amendments. The duty of the commodore is to take command when cruising in squadron, to preside at meetings, to enforce the rules and regulations, and he may call special meetings. The vice-commodore acts for him in his absence, and the rear-commodore in the event of both being absent. The latter two also take command of subdivisions of the fleet. The secretary keeps the records of the club, roll of members, list of yachts, etc., and does all the correspondence incidental to his duties. The treasurer takes charge of all dues, fines, and moneys, and keeps an account of the same, reporting at specified times to the club. The measurer takes the dimensions of yachts necessary to calculate their racing-measurement and time-allowance, for which he generally receives a fee to compensate for time and expense. On all matters concerning the yachts voting is restricted to owners; on general subjects all members have a vote. A regatta committee is also elected to arrange and supervise the details of all club regattas and matches, and also to act as judges, time-keepers, etc., for the same. The house committee looks after the club headquarters, annual dinners, etc., and the committee on membership reports for or against the propriety of electing applicants. The by-laws define the dues, when payable, when overdue, and how they are to be enforced. They specify dates and places of meetings, manner of notifying members, club-signals, hoisting colors, and discipline in general, compensation to officers, expulsions, publication of club-books, regatta-courses, etc.

SAILING RULES.

The most perfect and clearly-defined sailing rules, now universally accepted, are those adopted by the Yacht-Racing Association of Great Britain, and we cannot do better in America than accept them as they stand, barring the rule of measurement, which is open to the objections before noted. They are as follows:

1. *Management of races.*—All races, and all yachts sailing therein, shall be under the direction of the flag-officers or sailing committee of the club under whose auspices the races are being sailed. All matters shall be subject to their approval and control; and all doubts, questions, and disputes which may arise shall be subject to their decision. Their decisions shall be based upon these rules so far as they will apply, but as no rules can be devised capable of meeting every incident and accident of sailing, the sailing committee should keep in view the ordinary customs of the sea, and discourage all attempts to win a race by other means than fair sailing and superior speed and skill. The decisions of the sailing committee shall be final, unless they think fit, on the application of the parties interested, or otherwise, to refer the questions at issue for the decision of the council of the Yacht-Racing Association. No member of the sailing committee or council shall take part in the decision upon any disputed question in which he is directly interested. The sailing committee, or any officer appointed to take charge for the day, shall award the prizes subject to Rule 31. If any yacht be disqualified, the next in order shall be awarded the prize.

2. *Postponement of races.*—The sailing committee, or officer in charge for the day, shall have

power to postpone any race, should unfavorable weather render such a course desirable.

3. *Tonnage.*—Cites the English manner of measuring tonnage by multiplying length on load line, less the beam, by the beam, and again by the half beam. For this rule it is better to adopt some method more compatible with the needs of American yachts, such as the addition of length and beam, the multiplication of the two, the multiplication of all three cardinal dimensions, or something in conformity with the remarks at the close of this article. The rules of the Seawanhaka and Royal Nova Scotia Yacht Clubs will serve as guides where tonnage is estimated by a consideration of two or three dimensions.

4. *Time allowance.*—Time shall be allowed on arrival for difference in tonnage, according to the annexed scale, increased or decreased in proportion to the length of different courses.

Shortening course.—If it is necessary during a race to shorten the course, the signal-flag denoting the race hoisted under the white peter, or in case of fog or darkness two guns fired shall show that the race is to finish with the round about to be completed, and the time allowance shall be reduced in proportion.

5. *Entries.*—Entries shall be made with the secretary at least 48 hours previous to noon of the day appointed for starting each race. In case of a Sunday intervening, 24 hours shall be added. Entries may be made by telegram, and it shall be deemed sufficient that the same shall have been dispatched before noon of the day on which the entries close, subject to the provision as to Sundays.

Form of entry.—To be signed by the owner, or his representative, previous to the race:

Please to enter the yacht for the race at , on the . Her distinguishing flag is ; her rig is ; and her tonnage is tons. I undertake that while sailing under this entry she shall not have on board *any bags of shot;* that all her ballast shall be properly stowed under the platform or in lockers, and shall not be *shifted or trimmed in any way whatever;* and that I will obey and be bound by the Sailing Rules of the Yacht-Racing Association.

Races re-sailed.—Should any yacht duly entered for a race not start, or having started should she give up or be disabled during the race, such yacht shall, in the event of the race being re-sailed, be entitled to start; but no new entries shall be received under any circumstances whatever for a postponed race.

6. *Ownership.*—Each yacht entered for a race must be the *bona fide* property of the person or persons in whose name or names she is entered, who must be a member or members of a recognized yacht club.

7. *Only one yacht of same owner.*—No owner shall be allowed to enter more than one yacht in a race, except in cases in which a prize is given for each rig, when one yacht of each rig may be entered, nor shall he be entitled to enter the same yacht under different rigs for any race.

8. *One yacht entitled to sail over.*—When a prize has been offered for competition, any yacht duly entered may claim to sail over the course and shall be entitled to the prize; subject, however, to Rule 2.

9. *Sliding keels.*—No yachts which are fitted to shift keels, or to otherwise alter their form, shall be permitted to enter.

10. *Member on board.*—Every yacht sailing in a race shall have on board a member of a recognized yacht club, who, before the prize is awarded, shall sign a declaration that the yacht under his charge has strictly conformed to all the sailing regulations, as follows:

Declaration that rules have been observed.—I hereby declare that the yacht whilst sailing in the race this day, has strictly observed the sailing rules and regulations.

11. *Distinguishing flags.*—Each yacht must carry, at her main-topmast head, a rectangular distinguishing flag of a suitable size, which must not be hauled down unless she gives up the race. If the topmast be lowered on deck or carried away, the flag must be re-hoisted in a conspicuous place as soon as possible.

12. *Instructions.*—Every yacht entered for a race shall, at the time of entry, or as soon after as possible, be supplied with written or printed instructions as to the conditions of the race, the course to be sailed, marks, etc. Nothing shall be considered as a mark in the course unless specially named as such in these instructions.

13. *Sails.*—There shall be no restrictions as to sails, or the manner of setting and working them; but steam-power must not be used for hoisting sails.

14. *Crew and friends.*—There shall be no limit as to the number of paid hands, and no restrictions as to the number of friends, or to their working. No paid hand shall join or leave a yacht after the signal to start. [This rule is not intended to apply to Corinthian matches.]

15. *Fittings and ballast.*—All yachts exceeding 5 tons shall be fitted below deck with the ordinary fittings of a yacht, including two transverse bulk-heads of wood, and their platforms shall be kept down and bulk-heads standing. No water shall be started from or taken into the tanks after the signal to start has been made. No more than the usual anchors and chains shall be carried during a race, which must not be used as shifting ballast, or for altering the trim of the yacht. No bags of shot shall be on board, and all ballast shall be properly stowed under the platform or in lockers, and shall not be shifted or trimmed in any way whatever during a race. No ballast shall be shipped or unshipped after 9 P.M. of the day previous to the race. A race re-sailed shall, so far as regards this rule, be considered a new race.

16. *Boats and life-buoys.*—Every yacht exceeding 30 and under 70 tons, shall carry a boat on deck not less than 10 feet in length and 3 feet 6 inches beam, and every yacht of 70 tons and over, one of not less than 12 feet in length and 3 feet 6 inches beam, with oars lashed in them, ready for immediate use. Each yacht shall carry at least one life-buoy on deck ready for use.

17. *Starting.*—The yachts shall start from moorings, or under way, as directed by the sailing committee. Half an hour before the time of starting one of the following flags of the Commercial Code shall be hoisted as a preparative flag for the yachts of each successive race; in case of a start from anchors or moorings to take up their stations for the start with head-sails

down, or all sails down, as the sailing committee may direct; or in case the start be a flying one, to approach the starting-line, viz.:

B	of Commercial Code for the yachts of the	1st race.
C	....	2d "
D	....	3d "
F	....	4th "

and so on.

Signals to start.—Five minutes before the start the preparative flag shall be lowered, a blue peter hoisted, and a gun fired; after which, the yachts in the race shall be amenable to the rules. At the expiration of five minutes *exactly*, the blue peter shall be hauled down and a second gun fired as a signal to start. If the start is to be made from anchors or moorings, lots shall be drawn for stations, and springs shall be allowed on the same bridle or anchor chain or warp as the bow-fasts, but are not to be carried to a buoy, pier, other vessel, or fixed object.

Dragging moorings.—If any yacht lets go or parts her bridle before the signal to start, or if she drags any moorings or anchor to which she is made fast for the purpose of starting, she shall be liable to be disqualified, unless such parting or dragging be explained to the satisfaction of the committee, or unless she has returned, after the signal to start, within the line of starting-buoys, so as not to obtain any advantage by the accident.

Crossing the line.—In a flying start, if any yacht, or any part of her hull or spars, be on or across the line before the signal to start is made, she must return and recross the line; a yacht so returning, or one working into position from the wrong side of the line after the signal to start has been made, must keep clear of all competing yachts. Should the gun miss fire, the lowering of the blue peter shall be the signal to start.

18. *Meeting end-on.*—If two yachts are meeting end-on, or nearly end-on, so as to involve risk of collision, the helms of both shall be put to port, so that each may pass on the port side of the other.

19. *Two yachts crossing.*—When two yachts are crossing so as to involve risk of collision, then if they have the wind on different sides, the yacht with the wind on the port side shall keep out of the way of the yacht with the wind on the starboard side, except in the case in which the yacht with the wind on the port side is close-hauled and the other yacht free, in which case the latter yacht shall keep out of the way; but if they have the wind on the same side, or if one of them has the wind aft, then the yacht which is to windward shall keep out of the way of the yacht which is to leeward.

20. *Overtaking, rounding-marks, etc.*—A yacht overtaking another yacht shall keep out of the way of the last-mentioned yacht, but when rounding any buoy or vessel used to mark out the course, if two yachts are not clear of each other at the time the leading yacht is close to, and actually rounding the mark, the outside yacht must give the other room to pass clear of it, whether it be the lee or weather yacht which is in danger of fouling the mark. No yacht shall be considered clear of another yacht, unless so much ahead as to give a free choice to the other on which side she will pass. An overtaking yacht shall not, however, be justified in attempting to establish an overlap, and thus force a passage between the leading yacht and the mark after the latter yacht has altered her helm for the purpose of rounding.

21. *Obstructions to sea-room.*—When passing a pier, shoal, rock, vessel, or other obstruction to sea-room, should yachts not be clear of each other, the outside yacht or yachts must give room to the yacht in danger of fouling such obstruction, whether she be the weather or the leeward yacht; provided always that an overlap has been established before an obstruction is actually reached.

22. *Luffing and bearing away.*—A yacht may luff as she pleases to prevent another yacht passing to windward, but must never bear away out of her course to hinder the other passing to leeward,—the lee side to be considered that on which the leading yacht of the two carries her main-boom. The overtaking vessel, if to leeward, must not luff until she has drawn clear ahead of the yacht she has overtaken.

23. *Close-hauled approaching shore.*—If two yachts are standing towards a shore or shoal, or towards any buoy, boat, or vessel, and the yacht to leeward is likely to run aground, or foul of such buoy, boat, or vessel (a mark-vessel excepted), and is not able to tack without coming into collision with the yacht to windward, the latter shall at once tack, on being hailed to do so by the owner of the leeward yacht, or the person acting as his representative, who shall be bound to see that his own vessel tacks at the same time.

24. *Running aground, etc.*—Any yacht running on shore, or foul of a buoy, vessel, or other obstruction, may use her own anchors, boats, warps, etc., to get off, but may not receive any assistance except from the crew of the vessel fouled. Any anchor, boat, or warp used must be taken on board again before she continues the race.

25. *Fouling yachts, marks, etc.*—Each yacht must go fairly round the course; and must not touch any buoy, boat, or vessel used to mark it out, but shall not be disqualified if wrongfully compelled to do so by another yacht. Any yacht causing a mark-vessel to in any way shift her position to avoid being fouled by such yacht, shall be disqualified. If a yacht, in consequence of her neglect of any of these rules, shall foul another yacht, or compel other yachts to foul, she shall forfeit all claim to the prize, and shall pay all damages.

26. *Means of propulsion.*—No towing, sweeping, poling, or pushing, or any mode of propulsion except sails, shall be allowed.

27. *Anchoring.*—A yacht may anchor during a race, but must weigh her anchor again, and not slip. No yacht shall during a race make fast to any buoy, stage, or pier, or send an anchor out in a boat, except for the purpose of Rule 24.

28. *Sounding.*—No other means of sounding than the lead and line allowed.

29. *Side-lights.*—All yachts sailing in a race at night shall observe the Board of Trade rule as to the carrying of side-lights.

30. *Man overboard.*—In case of a man falling overboard from a competing yacht, all other yachts in a position to do so shall use their utmost endeavors to render assistance; and if it should appear that any yacht was thereby prevented winning the race, the committee shall have power to order it to be re-sailed between

any yacht or yachts so prevented and the actual winner.

31. *Protests.*—Should the owner of any yacht, or the person acting as his representative, consider that he has a fair ground of complaint against another for foul sailing, or any violation of these rules, he must, if it arise during the race, signify the same on first passing the committee vessel, by showing an ensign conspicuously in the main rigging. The protest shall be made in writing, and under such regulations (if any) as the sailing committee may have determined, within 12 hours of the arrival of the protesting yacht, and shall be heard by the sailing committee and decided, after such inquiries as they may consider necessary. They shall also, without a protest, disqualify any yacht, should it come to their knowledge that she has committed a breach of the rules.

32. *Removal of flag-boat.*—Should any flag-vessel or other mark be removed from its proper position, either by accident or design, the race shall be sailed over again, or not, at the discretion of the sailing committee.

33. *Penalty for disobeying rules.*—Any yacht disobeying or infringing any of these rules, which shall apply to all yachts whether sailing in the same or different races, shall be disqualified from receiving any prize she would otherwise have won, and her owner shall be liable for all damages arising therefrom.

Should a flagrant breach of these rules be proved against any yacht, her sailing-master may be disqualified by the council for one season from sailing in any race held under the Rules of the Yacht-Racing Association.

34. *Cruising trim.*—When yachts are ordered to sail in cruising trim, the following rules are to be strictly observed ;

1. No doors, tables, cabin skylights, or other cabin or deck fittings (davits excepted) shall be removed from their places before or during the race.

2. No sails or other gear shall be put into the main cabin in yachts exceeding 40 tons.

3. Anchors and chains suitable to the size of the yacht shall be carried, one at the cat-head (or in yachts of 40 tons and under, at the usual place on the bow), which anchor shall not be unshackled from the chain before or during the race.

4. Every yacht exceeding 30 and under 70 tons, shall carry a boat on deck not less than 10 feet in length and 3 feet 6 inches beam,—a yacht of 70 tons and over, her usual cutter and dinghey.

5. No extra hands, except a pilot, beyond the regular crew of the yacht, shall be allowed.

APPENDIX.

The Yacht-Racing Association further recommends for the consideration of sailing committees:

1st. *Allowance to schooners and yawls.*—That as mixed races are no satisfactory test of the relative speed of yachts, the different rigs should, whenever practicable, be kept separate; but when mixed races are unavoidable, the following rule shall be observed :

The tonnage of schooners and yawls to be reckoned for time allowance as follows, viz., schooners at three-fifths, and yawls at four-fifths of their actual tonnage ; provided that in case of a yawl, her main-boom when in its place and parallel to the deck, does not extend more than one-fifth her extreme beam abaft the aft side of her stern-post on deck. In calculating the deduction for difference of rig, the tonnage by certificate to the exact fraction to be used. The time allowances to be calculated from each vessel's reduced tonnage. Schooners and yawls shall not be allowed to enter in classes of 40 tons and under at the reduced tonnage.

2d. *Flying starts.*—That flying starts should be adopted when practicable, but no time should be allowed for delay in starting.

3d. *No limit to race.*—That any limit to the time for concluding a race should be avoided as far as possible.

4th *Classification.*—That the classification of yachts should, when practicable, be as follows :

Not exceeding	5 tons.
Above 5 tons and not exceeding	10 "
" 10 " " "	15 "
" 15 " " "	20 "
" 20 " " "	40 "
" 40 " " "	80 "
" 80 "	

5th. *Courses.*—That as distance is an important element in the calculation of time allowance, the marks and flag-boats should be placed so as to mark as accurately as possible the length of the course, for which time is allowed.

6th. *Rounding marks.*—That in heavy weather it should be arranged, if practicable, for yachts to stay instead of gybe round marks.

7th. *Room at starting.*—Sailing committees should be particularly careful to provide ample room between the points marking the starting-line.

Measurement.—The sole object of measurement and allowing time is to enable yachts of various sizes to compete upon terms of equality. A fair and logical rule must therefore be based upon size. Any rule which places a tax upon model is erroneous in foundation and misleading in its workings. Rules based upon any one or two dimensions, however much they may be the custom, are manifestly not equitable, because they do not tax differences of size, but differences of model in the one or two particular directions measured. They do not tax size because any one or any two dimensions added or multiplied are in no wise an expression of size, nor does such measurement necessarily represent the ratio of size between the vessels gauged. Yachts will shrink in the direction taxed, as witness the short, dumpy American sloop seeking to escape the penalty of length, and the English cutter squeezed into untaxed depth, the designer being restricted to their production against his will. A measurement of actual magnitude is the only mode which satisfies the fundamental proposition from which the reasoning takes its start. A rule taxing the actual size of a vessel does not in the slightest degree tax shape or model ; it taxes quantity only, and not its location. Under such a system the designer is left absolutely free, and can mold a given quantity into any shape he deems most desirable ; he may proportion length, beam, and depth to his taste, and a rival will not be compelled to pay unjustly because he may prefer some other shape, involving an excess in one or two directions without any excess in size. The rule of the New York Yacht Club is the most perfect in theory, and, so far as racing is

concerned, gives the fullest satisfaction. It calls for the measurement of the actual cubical contents of a yacht to the outside of her plank. There exists one objection to it in practical application. It does not admit of quick and ready gauging, nor can a yacht's size be easily verified upon the spot by an owner or a regatta committee. A simplification of the method of arriving at the same results with sufficient accuracy for practice is desirable. To this end a multiplication of all three chief dimensions, length, depth, and breadth, has been adopted with success by some clubs as a short-cut leading to like results. The correctness of this plan is based upon the assumption that the true size of all fast yachts bears so nearly a like proportion to their circumscribed solids that the products of the three extreme dimensions will express the ratio of their sizes to one another with sufficient accuracy for racing purposes. The only danger to be apprehended from a general and permanent adhesion to this rule arises from the probability of cutting down freeboard, and thereby decreasing the depth, and with it the racing size of yachts, whose owners would sail them only in fair weather. A long string of prizes won in midsummer breezes would be a strong inducement for others to follow suit, and one of the most desirable qualities of a cruising boat—ample freeboard—would be sacrificed to the greed for prizes. Should this fear turn out to be well grounded, the tendency can be counteracted by including in the rule of measurement a standard amount of freeboard, which would at once remove the inducement to cripple cruising efficiency in the manner indicated. The rule and allowances of the New York Yacht Club are as follows:

TABLE OF ALLOWANCES

In Minutes and Decimals, by a Yacht measuring Sixteen Thousand Cubic Feet, to Yachts of the Measurements given below.

Cubic Feet.	Allowances.	Cubic Feet.	Allowances.	Cubic Feet.	Allowances.	Cubic Feet.	Allowances.	Cubic Feet.	Allowances.	Cubic Feet.	Allowances.	Cubic Feet.	Allowances.	Cubic Feet.	Allowances.

The water-line of each yacht shall be divided into four equal parts, and a section taken at each point of division, making five sections. The area of each section, from the rabbet-line of the keel to the line of the lowest point of the top of the plank-shear, as described in the rules, shall be measured and determined in square feet, and the cubical contents of the yacht shall then be got by the following formula taken from Chapman's rules for measuring vessels:

To the sum of the areas of the first and last sections add the sum of the areas of the even sections multiplied by 4, and the areas of the odd sections multiplied by 2. Multiply this sum by one-third of the distance between the sections, and add the cubical contents of the overhangs, measured in each case, as shall, from the form of the boat, be most expedient, and the result thus obtained shall, for the purposes of this measurement, be deemed the cubical contents of the yacht.

To find the allowance to a yacht whose measurement comes between any two even hundreds in the tables, deduct from the allowance to the even hundreds next below hers, such proportion of the difference between that allowance and the one next above it in the table as the excess of her measurement over the lower hundred bears to one hundred.—*C. P. Kunhardt, N.A.*

Yarage. The power of moving or being managed at sea; said with reference to a ship.

Yard. A spar suspended from a mast, to which the head of a sail is bent. Stun'sail-yards are suspended from the yard-arms by their halliards. The centre of a yard is called the *slings*, the extremities, the *yard-arms*, and the intermediate parts, the *quarters*. Yards for lateen- and lug-sails have their halliards bent on near the forward end; yards for square-sails are supported at their centres by slings, tyes, or halliards, and at the extremities by lifts. Lower yards are fixed, being attached to the mast by trusses, which permit angular movement only; all other yards are confined to the masts by parrels, which permit a vertical as well as an angular movement of the yards. Yards are hoisted by halliards, and trimmed by braces. *Lower yards* are supported by the lower-masts; *topsail-yards*,

topgallant-yards, and *royal-yards* follow in order, and traverse up and down their respective masts. *Skysail-yards* are sometimes carried, and are placed next above the royals. A *gaff-topsail yard* is a small yard to which the head of a gaff-topsail is sometimes bent.

Yard is also the popular name given to the three stars in Orion's belt. See NAVY-YARD.

YARD-ARM. The extremity of a yard. *Yard-arm and yard-arm*, the situation of ships close alongside each other.

YARD-ARM CLEATS. Wooden wedges nailed to the yard-arm to prevent the lifts and braces from slipping in.

YARD-ROPE. A rope bent to the slings of a yard by which it is swayed aloft or lowered.

YARD-TACKLE. A heavy tackle hooked to lower yards, and used in hoisting heavy articles in or out.

Yare. *Be yare at the helm!* quick with the helm!—an old nautical phrase

Yarmouth, County of Norfolk, England, is situated on a narrow strip of land between the sea and the river Yare. The quay, considered one of the finest in Britain, extends along the river for about 1 mile. On the coast are several batteries and barracks for 1000 men. The harbor is in the Yare, and is accessible by vessels of about 200 tons, and the navigation of the coast is dangerous, but Yarmouth Roads, which extend between the coast and a line of sand-banks a short distance off shore, are a safe anchorage. Ship-building is carried on, and it has a manufactory of silk goods, but the principal industry is the herring-fishery, and as much as 9000 tons of fish have been shipped from here in a year. Pop. 35,000.

YARMOUTH CAPON. A red herring; a bloater.

YARMOUTH HERRING-BOAT. A clinch-built boat with lug-sails, used in the herring-fishery.

Yarn. A rope-yarn. A tale; a story. *To spin a yarn*, to relate a story.

Yaugh. An old term for a small yacht.

Yaw. To deviate from the course. Yawing is caused by a heavy sea under the quarter, by bad steering, or by an injudicious arrangement of the sails.

YAW-SIGHTED. Squint-eyed.

Yawl. A small fishing-vessel. A carvel-built vessel of the cutter class with a jigger and short main-boom. An English man-of-war's boat, carvel-built, and pulling generally 12 oars.

Yaw-yaws. A nickname for seamen from the Baltic.

Year. The period in which the earth completes a revolution in her orbit. Some point must be taken to mark the origin whence the revolution is reckoned; if a fixed star be taken, the period is called a *sidereal* year ($365^d\ 6^h\ 9^m\ 9.6^s$); if the first point of Aries, the period is known as the *solar*, *equinoctial*, or *tropical* year ($365^d\ 5^h\ 48^m\ 49.7^s$). The *anomalistic* year is the period between two successive returns of the earth to perihelion. The *civil* year consists of an integral number of days,—a common of 365 and leap-year of 366 days. See CALENDAR.

Yell. An old sea-term to express a rolling motion.

Yellow Admiral (*Eng.*). A retired post-captain who, not having served his time in that rank, is not entitled to promotion.

Yellow-belly. A dago; a mulatto.

Yellow Fever (*Typhus icterodes*, *fièvre jaune*, *fiebre amarilla*, *gelbesfieber*, *mal de Siam*, *etc.*). An acute, specific, infectious disease, of a single paroxysm and remarkable malignancy, originating on the coasts and included islands of the great intercontinental gulf of the western hemisphere, as does cholera in those of the Indo-Chinese gulf. Like cholera also, it spreads from its region of origin (the "yellow fever zone"), following the paths of commerce, into other parts of the world, but never becomes naturalized (endemic) outside of its geographical habitat. It is limited to the neighborhood of the sea, and to elevations not exceeding 2500 feet. For its continued activity are required a temperature not below 72° F., a humid atmosphere, the presence of its specific cause and of decomposing organic matter, and, probably, a peculiar but unknown meteorological condition (perhaps, as suggested by Dr. Findlay, of Havana, a highly alkaline atmosphere).

Yellow fever is mentioned as attacking the Spanish *conquistadores*, at San Domingo, in 1494; and is first recorded at Porto Rico in 1508, Darien in 1514, Guadaloupe in 1635, Martinique in 1641, Havana in 1761, etc. It was introduced into Rio de Janeiro and the west coast of South America about 1849, by the stream of travel attracted to California at the time of the gold excitement, and, like many an exotic plant, has often flourished more vigorously in its new than in its old home. The name *mal de Siam* originates from its supposed introduction into Martinique from that country by the "Oriflamme," in 1690. The "Oriflamme" did not, however, come directly from Siam, and yellow fever had certainly appeared in Martinique as early as 1641. Increased commerce has facilitated the dissemination of the yellow fever poison, which is as portable as merchandise, until there is now scarcely a port within its climatic limits which has not suffered from one or more epidemics. Notable examples are the epidemics at Philadelphia in 1793, Gibraltar in 1828, New Orleans in 1853, and Memphis in 1878–79, which are considered as epochs in the history of yellow fever, from the fact that each has been reported upon by observers of remarkable trustworthiness (Drs. Benj. Rush, Simon, E. H. Barton, and the National Board of Health). The importance of yellow fever from a military stand-point attaches rather to the navy than to the army, since soldiers can always be moved from an unhealthy locality and segregated from sources of infection. Its terrors are immeasurably augmented when they invade the inhabitants of a ship at sea, where the sick cannot be separated from the well, and all possibility of escape by flight is cut off, while close crowding affords great facilities to its increase. An early instance in the history of the U. S. navy was the ship "Gen. Green," in which yellow fever appeared while making a voyage from Newport to Havana, in 1799, and, notwithstanding efforts at disinfection at the mouth of the Chesapeake on her homeward voyage, reappeared at sea, and continued to spread while she lay at Newport, attacking even those who bathed near the ship. The "Macedonian" suffered from yellow fever at Havana, in May, 1822, so severely, that she returned to Norfolk in July, and was put out of commission. Of 376 persons on board, 101 died in this short time.

Yellow fever appeared on board of the British steamer "Éclair," at Sierra Leone, in 1845, whence she sailed to Boa Vista. There the disease spread rapidly, although the crew was landed on an island, and of 4 officers from the "Growler," who visited the empty ship as a board of survey, 3 had yellow fever. She returned to England in September, having 41 cases at sea. The pilot who boarded her was attacked. In 1847, after having been cleansed and disinfected, the "Éclair" sailed for the Cape of Good Hope, but was obliged to put in at Ascension with yellow fever again on board. The "Susquehanna" suffered from yellow fever at Grey Town in 1856, and landed 200 cases at Jamaica and New York. She was repeatedly broken out, cleansed, and exposed to a freezing temperature, to be finally abandoned as incorrigibly infected. The "Plymouth" had a return of yellow fever in the spring of 1879, before touching at any port, after having been broken out, disinfected, and exposed to the low temperature of Boston during most of the preceding winter. At this writing (May, 1880) the "Marion" is reported at Montevideo, with yellow fever on board, undergoing disinfection. Of late years the ports of Havana, Rio de Janeiro, and St. Thomas have most frequently been credited with being the sources of yellow fever epidemics, the two latter, in particular, so far as men-of-war are concerned. Severe naval epidemics have also occurred at the navy-yard, Pensacola, and at Key West.

Yellow fever is characterized by a period of incubation seldom exceeding 5 days, a sudden and prostrating onset, with high body temperature (105°–107° F.), flushed face, suffusion of the eyes, and albuminous urine, deficient in chlorides. To the paroxysm, which lasts from 24 to 48 hours, succeeds a "stage of calm," during which the fever subsides, hemorrhages occur from the nose, gums, stomach (black vomit), and intestines (tarry stools), and a yellow tint colors the whole surface, deepening during convalescence or after death. Renewal of fever, or a sudden rise in body temperature, indicate a fatal termination, which generally occurs between the fourth and seventh day. After death there is a notable rise in the body temperature (to 106° F.), which lasts for 12 hours, putrefaction progresses rapidly, and an odor, said to be peculiar to the disease, is developed. The blood is found to be thin, fluid, of acid reaction, with its white corpuscles increased in number and undergoing fatty degeneration. It is said to contain a great excess of urea (Dr. Joseph Jones, of New Orleans). The liver is also subject to fatty degeneration, and presents a fawn-yellow color. Lesions have been observed in the kidneys, spleen, and nervous system, but are not invariably characteristic of this disease. No peculiar organism has yet been discovered in the blood of yellow fever patients where proper precautions against its artificial introduction have been observed. When death does not occur, convalescence is tedious, and likely to be interrupted by changes of weather or slight imprudence, the blood having become profoundly impaired as to its nutritive functions during the paroxysm. There is no drug which has been proved to be a specific cure, the most successful treatment confining itself to hygienic measures, fluid diet, promotion of perspiration, and a free use of ice.

The *cause* of yellow fever has not yet been discovered. It is, however, known to be portable and specific (reproducing its like and no other disease), is almost certainly material, and is very probably either a living organism or a substance resulting therefrom (as alcohol, acetic and lactic acids result from the growth of fungi and bacteria). It is capable of lying dormant indefinitely under a low temperature and unfavorable conditions, to revive when congenial surroundings are restored. In this regard it suggests a parallel with the passive forms of many fungi. Decomposing organic matter, coal, and especially decaying sea-weed and rotten wood, favor its development, wood affected with dry rot (see DRY ROT) appearing to afford peculiar facilities to its preservation in a dormant state.

Prevention should include such construction as will obstruct the development of dry rot and afford no inaccessible recesses in a ship, cleanliness, ventilation, anchorage at a distance from shore, and a rigid observance of sanitary regulations relating to intercourse with the shore, clothing, food, hours of labor, and fresh-water supply.

Disinfection by chemicals, such as carbolic acid, chlorine, sulphate of iron, etc., has not proved satisfactory, the foul odors which these agents destroy having no necessary connection with yellow fever. Exposure to a low temperature causes the disease to cease for the time, but has not always prevented its later recurrence, as in the cases of the "Susquehanna" and "Plymouth," and experiments upon low organisms found to be connected with other diseases have shown that their vitality is not destroyed even by so low a temperature as —10° F. Live steam was injected into the holds of the "Don" (at Santa Cruz) and "Mahaska" (at New Orleans) in 1867, with success, the vessels remaining on the station without any return of the disease. Sulphurous acid gas and air at a temperature exceeding 260° F. have been found to be alike fatal to all living organisms, and a naval board ordered to investigate the subject, has this year (1880) recommended the use of this gas, superheated, in the holds of infected vessels. Billings, U.S.A., in *Contemporary Review*, January, 1880, etc.)—*J. H. Kidder*, *Surgeon U.S.N.*

Yellowing (*Eng.*). The overslaughing of captains in a flag-promotion.

Yellow Jack. Yellow fever. The quarantine flag.

Yellow Tail. A well-known tropical fish, often in company with whip-rays; it is about 4 feet long, with a great head, large eyes, and many fins.

Yeo-heave-yeo! The chant of merchant sailors in hauling and heaving.

Yeoman. An appointed officer who has charge of stores and keeps the accounts in his special department; as, ship's yeoman, paymaster's yeoman, engineer's yeoman.

Yoke. An athwartship piece of wood or metal fitted over the head of a boat's rudder, and serving as a substitute for a tiller.

YOKE-LINES. Lines from each extremity of a yoke and extending to the stern-sheets, and used in steering a boat.

Young Gentlemen. A general designation for midshipmen.

Young Ice. Ice recently formed.

Youngsters. A general term for young officers, or men. See OLDSTER.

Young Wind. The commencement of the land- or sea-breeze.

Yow-yow. A small Chinese sampan.

Z.

Z. In the log-book, *z* denotes *haze*.

Zambo. A sobriquet on the Spanish Main for a race produced by the union of the negro and the Indian; it literally means bow-legged.

Zenith. The superior pole of the celestial horizon; the point of the heavens directly overhead.

ZENITH-DISTANCE. The angular distance of a heavenly body from the zenith; the complement of the altitude.

Zephyr. The west wind. A gentle breeze.

Zero. The point from which the marks on a graduated scale are numbered, the marks progressing in one direction being read *plus*, and those in the contrary direction *minus*. A zero as a point of reference may be established arbitrarily. The *absolute zero* of temperature, the most convenient base for scientific computations, as computed from the apparent law of expansion of a perfect gas, is 461.2 degrees below the zero of Fahrenheit.

Zodiac (Gr., from *zōdion*, the diminutive of *zōon*, an animal). That region of the heavens within which the apparent motions of the sun, moon, and the most conspicuous of the planets are confined. The apparent paths of the moon and all the known planets were found to be spiral curves of more or less complexity, and described with very unequal velocities in their different parts. These bodies were observed, however, to have this in common, that the general direction of their motions is the same with that of the sun, viz., from west to east, contrary to that in which both they and the stars appear to be carried by the diurnal motion of the heavens; and, moreover, that they cross and recross the ecliptic at regular and equal intervals of time, never deviating from the ecliptic on either side more than 8° or 9°. It is this zone of about 17° broad, having the ecliptic running along its middle, which was named the zodiac. Before the discovery of the asteroids, the zodiac restricted to the above limits formed the zone of the moving bodies of the heavens. But the orbits of many of the asteroids have a very considerable inclination to the ecliptic,—Pallas nearly 35°, so that the significance of the zone of the zodiac is now, except in the most general sense, all but obsolete. The term zodiac is derived from the constellations of this zone being anciently figured as "animals." Its circuit was divided into 12 equal parts, the "sign" or symbol of each being taken from the constellation with which it then coincided. They are as follows:

NORTHERN SIGNS.

♈ *Aries*, the Ram.	♋ *Cancer*, the Crab.
♉ *Taurus*, the Bull.	♌ *Leo*, the Lion.
♊ *Gemini*, the Twins.	♍ *Virgo*, the Virgin.

SOUTHERN SIGNS.

♎ *Libra*, the Balance.	♑ *Capricornus*, the Goat.
♏ *Scorpio*, the Scorpion.	♒ *Aquarius*, the Water-bearer.
♐ *Sagittarius*, the Archer.	♓ *Pisces*, the Fishes.

These constellations, however, do not cover the same parts of the ecliptic they formerly did, in consequence of the retrograde motion of the first point of Aries along the ecliptic, from which its divisions are reckoned. Hence the necessity of distinguishing between the *signs* of the ecliptic or zodiac and the *constellations* of the zodiac, the former being purely technical subdivisions of ecliptic of 30° each, commencing from the first point of Aries.

ZODIACAL LIGHT. A cone of faint light apparently proceeding from the rising or the setting sun; it is most commonly seen in the tropics.

Zoel, or Saul. A timber much used in the construction of the vessels of India.

Zone (Gr. *zōnē*, a belt). In consequence of the obliquity of the ecliptic, the earth's surface is naturally divided into 5 zones. The *torrid* zone embraces the region situated between the parallels 23° 28′ N., and 23° 28′ S.; at some season of the year the sun will be in the zenith of each point of this region. The *temperate* zones extend from the torrid zone to the parallels 66° 32′ N., and 66° 32′ S.; the sun is seen to rise every day, and it is never in the zenith of any point of these zones. The *frigid* zones extend from the poles to the temperate zones; at some time during the year the sun will be below the horizon for more than 24 hours, and at another time it will be above the horizon for more than 24 hours, the length of this time depending upon the proximity of the point to the pole.

Zopissa. Tar or pitch scraped off the bottoms of old ships, and thought to be good for ulcers. Also, a highly preservative varnish in use by the ancients for ship's bottoms, sarcophagi, etc.

Zuben el Chamali. *β Libræ.*

Zuben el Genubi. *α Libræ.*

Zuhn. A species of rush from which inferior canvas and cordage is made, in the East.

Zumbra. A small Spanish row-boat.
